The authors would like to thank field supervisors, interviewers and lab staff from the Provincial Centers for AIDS control, Provincial AIDS Committees, and the Provincial Centers for Preventive Medicine in An Giang, Can Tho, Da Nang, Dien Bien, Dong Nai, Hai Phong, Ha Noi, Ho Chi Minh City, Lao Cai, Nghe An, Quang Ninh, and Yen Bai for their support for the study team during field implementation. They also would like to express special thanks to Patrick Nadol (CDC) and Dang Vu Trung (USAID) for their invaluable comments on the report.

The IBBS publication has been produced with the generous support of the American people through the United States Agency for International Development (USAID) and the Centers for Disease Control and Prevention (CDC). The contents are the responsibility of the authors and do not necessarily reflect the views of USAID, CDC or the United States Government.

### Introduction

The HIV epidemic in Viet Nam is as a concentrated phase. However, individual provinces have taken on unique epidemiological characteristics, such that the epidemic can be characterized as a conglomerate of localized epidemics.

Surveillance systems enable governments and key stakeholders to trace the nature of epidemics and changes among target populations. National HIV/AIDS Sentinel Surveillance System in Vietnam was established in 1994, with sentinel serological surveillance in 40 provinces/cities. The sentinel surveillance system has been providing important information on HIV prevalence trends in Viet Nam. However, the results from the sentinel surveillance system do not provide enough information about the factors that impact these HIV trends.

Between 2000 and 2001, two rounds of behavioral surveillance were conducted in five provinces including Hanoi, Hai Phong, Quang Ninh, Ho Chi Minh City, and Can Tho. This early-warning system could provide important behavior indicators that can predict the future course of HIV epidemic. As part of an effort to improve epidemic tracking and program planning, the first Integrated Biological and Behavioral Surveillance was conducted between 2005 and 2006 in the five provinces above, with the addition of Da Nang and An Giang. This community-based systematic survey was designed to assess risk behaviors and HIV and other STI prevalence among most-at-risk populations, specifically injecting drug users, female sex workers, and men who have sex with men.

During 2009 – 2010, under the direction of Vietnam Authority for AIDS Control, the National Institute of Hygiene and Epidemiology implemented the IBBS round II among Injecting Drug Users (IDUs), Female Sex Workers (FSWs) and Men Who Have Sex with Men (MSM) in seven provinces that were covered by the IBBS round I as well as five new provinces, which included Nghe An, Yen Bai, Dong Nai, Dien Bien, and Lao Cai. The IBBS provided information for 8 indicators among the 21 indicators required by the United Nations (UN). The IBBS is an important study that not only provides information on HIV/STI epidemics in Viet Nam in order to help improve interventions as well as reports to the UN, but also to estimate the HIV incidence rate in order to better monitor HIV transmission among populations most at risk and the Hepatitis B and Hepatitis C prevalence, which are associated with human liver cancer.

The joint collaborators would like to thank the Provincial AIDS Centers, regional Pasteur Institutes, program officers, data collectors and analysts, who were directly involved in surveillance and analysis, for their cooperation. Gracious thanks are also provided to the agencies of the President's Emergency Plan for AIDS Relief (PEPFAR), including the United States Agency for International Development (USAID), the United States Centers for Disease Control and Prevention (CDC), and to FHI 360 and the United Nations Office on Drugs and Crime (UNODC) for financial and technical support.

A.Prof, NGUYEN TRAN HIEN, MD, PhD

# **Executive Summary**

From June 2009 to February 2010, Vietnam's second round of integrated HIV/STI biological and behavioral surveillance (IBBS) was conducted among select population groups in Ha Noi, Hai Phong, Quang Ninh, Ho Chi Minh City, Can Tho, An Giang, Da Nang, Nghe An, Yen Bai, Dong Nai, Dien Bien and Lao Cai. The IBBS utilized community-based sampling to estimate the prevalence of HIV and other sexually transmitted infections (STI) and to provide indicators of risk behaviors and intervention exposure among most-at-risk populations (MARP). These included injecting drug users (IDU), female sex workers (FSWs), and men who have sex with men (MSM). The cross-sectional surveys employed time-location sampling (TLS) and respondent-driven sampling (RDS) to recruit 3,638 IDUs in 12 provinces, 5,458 FSWs in 10 provinces, and 1,596 MSM in four provinces. Behavioral and other data were collected through individual face-to-face interviews, while the prevalence of HIV and STI were selectively measured by testing blood, urine, and rectal swab samples. Results were compared to the 2006 IBBS surveys to determine changes in HIV infection, risk and preventive behaviors, and service access among the MARPs.

**Injecting drug users:** Potential stabilization of high HIV prevalence in some provinces, but needle sharing remains high, while condom use remains low

In the seven provinces with surveys conducted in both 2006 and 2009, only HCMC had increased HIV prevalence significantly from 34% to 46%, while Hai Phong and Can Tho had decreased significantly. HIV prevalence in An Giang had increased but not significant. Ha Noi, Da Nang and Quang Ninh had decreased but not significant. HCMC IDUs prevalence increased from 34% to 46%, yet prevalence among recent injectors declined from 28% in 2006 to 5% in 2009, suggesting preliminary evidence for a decline in incidence. Hai Phong had the largest decrease in prevalence, from 66% to 48%. Although there has been an overall decrease in HIV prevalence, infection levels remained high in all provinces surveyed, ranging from 16% prevalence in An Giang to 56% prevalence in Dien Bien. The one exception is Da Nang with 1% prevalence.

Needle and syringe sharing was relatively high in most provinces surveyed, with a median 24% of IDUs reporting sharing in the last six months and 15% in the past one month. Over 20% of IDUs reported sharing in the last six months in all but three provinces (Hai Phong, Can Tho and An Giang), and up to 35% in Lao Cai. As would be expected and concerning among HIV-positive IDUs, the majority (up to 82% in Quang Ninh) reported having ever shared needles and syringes, except in An Giang and Hai Phong. Compared with data from 2006, in 2009 needle sharing in the last six months decreased in Hai Phong, HCMC, Can Tho, and An Giang, increased in Ha Noi and Quang Ninh, and remained the same in Da Nang.

Consistent condom use, defined as having used a condom in all sexual contact. proportion of consistent condom use in the past 12 months among IDUs was lower for sex with regular partners, i.e. wives and girlfriends (ranging from 15% to 56%), than with FSWs (ranging 39% to 84%). Among IDUs who were HIV infected, sample sizes in several provinces were too small to conclude definitively, yet results indicated roughly one-third did not consistently use condoms with regular sex partners. Sexual risk practices with FSWs have changed little

since 2006, with the exception of an increase in consistent condom use in An Giang (45% to 73%), and a decrease in Quang Ninh (81% to 69%).

In all provinces but Ha Noi, the proportion of IDUs who were tested and were aware of their HIV status was significantly higher in 2009 than in 2006. Quang Ninh and Da Nang saw the largest increases, more than two-fold and three-fold, respectively. Despite these increases, fewer than 30% of IDUs accessed counseling and testing services in the majority of provinces. Access to and/or utilization of free needle/syringe programs was limited. Fewer than half of the IDUs in 8 of the 12 provinces surveyed had obtained free needles/syringes in the last six months and less than one-third in five of the provinces.

Female sex workers: Critical risk factors such as inconsistent condom use and drug injection are common

HIV prevalence among FSWs varied considerably by province and classification (street-based versus venue-based). In most provinces, street-based sex workers (SSWs) had higher HIV prevalence than venue-based sex workers (VSWs). Prevalence exceeded 10% in Ha Noi, Hai Phong, and HCMC in both sex work subpopulations and in Can Tho and Yen Bai among street-based sex workers (SSWs). Both SSWs and VSWs in Quang Ninh, Nghe An and Da Nang have prevalences of 3% or below. SSWs in Hai Phong had the highest prevalence at 23%. Although the reported number of drug users among study respondents were too small to detect statistical significance in most provinces, HIV infection remains strongly associated with drug injection among FSWs (e.g. 78% of injecting SSWs in Can Tho were HIV-positive, versus 8% of non-injecting SSWs). Compared to the 2006 IBBS, HIV prevalence among FSWs increased considerably for sub-groups in some provinces, and decreased for others. Prevalence increased significant among VSWs in Ha Noi (9.4% vs. 17.7%) and Hai Phong (5% vs. 11.7%) and HCMC (6% vs. 16%). The decreasing significant was seen in An Giang (10% vs. 3%), but not significant in Can Tho, Da Nang and Quang Ninh.

IBBS 2009 had documented HIV prevalence among SSWs had decreased significant in Can Tho (29% vs. 20%), and Quang Ninh (12.4% vs 1.3%). This figure also was reported the increasing significant among SSWs in HCMC (11% vs. 16%) and Hai Phong (7% vs. 23%). In An Giang, Da Nang and Ha Noi had no significant.

STI prevalence differed between the two provinces for which full data were collected (Ha Noi and HCMC). While N. gonorrhea and Chlamydia prevalence for both SSWs and VSWs in Ha Noi in 2009 are lower than in 2006, Chlamydia prevalence for SSWs in HCMC is higher in 2009 (11%) than in in 2006 (6%). Gonorrhea prevalence was low and relatively rare in both cities. Syphilis prevalence remains low among FSWs, at less than 2% in all 10 provinces surveyed.

While condom use with regular clients at last sex was reportedly high in most provinces, consistent condom use in the last month varied considerably, and was particularly low in Ha Noi, HCMC and Dong Nai. FSWs reported using condoms more consistently with one-time clients than with regular clients. Data from Ha Noi and HCMC are concerning. For both SSWs and VSWs, consistent condom use dropped considerably both for one-time and regular

clients. In HCMC, consistent condom use among SSWs more than halved from 69% to 31% for one-time clients, and 64% to 27% for regular clients.

Drug injection is an increasingly critical risk factor for HIV transmission among FSWs, and is considerably high in Ha Noi, Hai Phong, HCMC, and Can Tho. SSWs were much more likely to report drug injection than VSWs (8% vs. 13% in HCMC; 5% vs. 15% in Ha Noi; 4% vs. 18% in Hai Phong and 1% vs. 16% in Can Tho).

Over 10% SSWs in 4 provinces reported having IDU partner and over 5% were reported in 9 provinces, special in Ha Noi, this proportion is more than 20%. Among VSWs in Ha Noi, 12% had reported having IDU partner, this is a highest figure in all provinces.

HIV testing increased among FSWs, but remained low in all provinces except a few e.g. Hai Phong, Da Nang and Nghe An. SSWs were more likely to test for and receive their results than VSWs. Testing in the newly surveyed provinces of Lao Cai and Yen Bai was significantly lower than other provinces. Disaggregation of data between VSWs and SSWs shows differences in access to cheap/free condoms for the two subgroups in a number of provinces. Overall, a higher proportion of SSWs reported accessing cheap/free condoms. Over 80% of SSWs in Hai Phong, An Giang, Can Tho and Nghe An reported accessing cheap/free condoms in the last six months.

#### Men who have sex with men: HIV and STI infection remains high, risks remain multiple

HIV prevalence among MSM was greater than 10% in three of the four provinces surveyed, and as high as 20% (MSM who had not sold sex - Ha Noi). In Ha Noi and HCMC, HIV prevalence among both groups of MSM who had and had not sold sex in 2009 was significantly higher than in 2006. STI infection among MSM remains high in three of the four provinces surveyed, despite a small decrease from 2006 to 2009 in Ha Noi. One in five MSM in HCMC was infected with at least one STI, and nearly one in five in Can Tho and Ha Noi.

MSM have a variety of sexual partnerships. Those who sold sex had more consensual sexual partnerships with women in the past year in three of the four provinces surveyed (48% to 56%) than those who did not sell sex (23% to 40%). MSM who sold sex were also more likely to report sex with FSWs (up to 25% compared to 11% among those not selling sex in Can Tho). MSM who did not sell sex generally preferred consensual male sexual partners, though a substantial number reported sexual relations with consensual female partners (from 23-40%).

Consistent condom use in the last 12 months varied among MSM, but was concerningly low for MSM who sold sex - under 50% with any type of sex partners in all cities except Ha Noi, where 64% reported consistent condom use with FSWs. Condom use with consensual female partners was lower than with consensual male partners. Comparisons of data between IBBS Rounds I and II show diverse results for Ha Noi and HCMC. Condom use among MSM who sold sex in Ha Noi was higher in 2009 than in 2006 for all types of partners. Conversely, consistent condom use in HCMC dropped precipitously for male clients and consensual male partners, and from 26% to 19% for consensual female partners. Among MSM who did not sell sex in Ha Noi, consistent condom use increased dramatically with consensual male sex partners (more than doubled).

Like FSWs and IDUs, MSM face drug-related risks that increase their chances of acquiring HIV. Drug use ranged from one in ten (Can Tho) to one in three (Ha Noi). Reported drug injection was comparatively low (highest at 8% in HCMC). More than twice as many druginjecting MSM were HIV-positive in Ha Noi compared to those who did not inject. Data for Can Tho were similar, while MSM who injected in HCMC had slightly higher HIV prevalence than those who did not.

Testing for MSM was low (less than 30%) in all four MSM provinces surveyed. HCMC saw a substantial decrease (from 24% to 19%) in the proportion of MSM tested and returned their results from 2006 to 2009.

Forty-two to 65% of MSM surveyed in Ha Noi, HCMC and Can Tho reported obtaining free condoms within the last six months. The proportion of MSM in Hai Phong was comparatively lower, especially among MSM who had sold sex for money (7%). A comparison of data from 2006 and 2009 shows that obtainment of free condoms among MSM has increase in both Ha Noi and HCMC.

# Objectives

- 1. Measure and monitor changes in HIV/STI prevalence among most-at-risk populations including FSWs, IDUs, and MSM in 12 city/provinces include Ha Noi, Hai Phong, Quang Ninh, Nghe An, Yen Bai, Lao Cai, Dien Bien, Da Nang, Dong Nai, HCMC, Can Tho and An Giang.
- 2. Measure and monitor changes in behaviors related to HIV/STI transmission, including safe and high-risk behaviors among most -at-risk population in selected city/provinces.
- 3. Estimate the coverage of HIV/AIDS interventions in study provinces

## Methods

#### I. STUDY DESIGN

To ensure that IBBS data from Round II would be comparable to data from Round I, the team employed similar study design to that used in the first round. Round II employed a cross-sectional design to sample participants from communities in select provinces. Data included information on behaviors and intervention exposure through direct, one-on-one interviews by trained interviewers, and biological data sampled by blood, urine, and rectal swabs. Cross-sectional surveys were repeated in target populations in study sites selected from Round I, which were conducted from December 2005 to June 2006. Sampling methods included time-location sampling (TLS) and respondent-driven sampling (RDS). Blood samples were collected for HIV and syphilis testing in all populations. Urine samples and rectal swabs were collected to test for N. gonorrhea and C.trachomatis among FSWs and MSM in selected provinces.

Data collection was conducted from June 2009 to feb 2010

#### II. TARGET POPULATIONS

#### *Injecting drug users (IDUs)*

The study recruited men aged 18 years or older who reported injecting drugs in the last month, who were accessible at the time of the survey, who were willing to participate in the study, and who agreed to provide specimens for HIV/STI testing.

#### Female sex workers (FSWs)

This study recruited women based on the following criteria: women who were aged 18 years or older, who reported exchanging sex for money at least once within one month prior to the survey, who worked on the street (as street-based sex workers) or in venues such as karaoke or massage bars (as venue-based sex workers), who were willing to participate in the study, and who agreed to provide specimens for HIV/STI testing. Although some sex workers were sampled at entertainment venues, they were characterized as street-based sex workers in this study based on the most common means of meeting clients. For example, in Hai Phong, some sex workers who were sampled at entertainment venues were characterized as street-based sex workers because they had moved off the street temporarily to avoid government campaigns against 'social evils'.

#### *Men who have sex with men (MSM)*

MSM who participated in the study were men aged 15 years or older, who engaged in sex with men at least once in the previous 12 months, who were willing to participate in the study, and who agreed to provide specimens for HIV/STI testing. MSM were sampled without targeting men who had sold sex. However, because a large proportion of the sample had reported selling sex in the past month (see section VIII.2.2 for potential sampling issues), this report provides two sets of results for those who had (MSW) and had not (non-MSW) received payment for sex in the past one month.

#### III. STUDY SITES

The 2009 IBBS added five additional provinces to the seven surveyed in 2006: Nghe An, Yen Bai, Lao Cai, Dien Bien and Dong Nai. These provinces were included because they have complicated epidemics and are the locations of comprehensive interventions supported by donors, including PEPFAR, the World Bank, and the Global Fund. See *Table* 1 for a complete list of provinces and districts surveyed.

**Table 1:** Participant recruitment sites by study population

Provinces	IDUs	FSWs	MSM	Districts/cities (study sites)
Ha Noi	✓	✓	✓	Dong Da, Hai Ba Trung, Thanh Xuan, Cau Giay

<sup>\*</sup> New sites in 2009

#### IV. STUDY INDICATORS

The basic indicators used in Round I were unchanged in Round II. Timeframes for some indicators were altered to match the national program or UNGASS indicators. The study indicators included the following:

- HIV/AIDS knowledge and attitudes
- Knowledge of STIs and STI care-seeking behaviors
- Other practices related to condom use and safe sex
- Condom use with different types of sex partners

<sup>14</sup> 

- Sexual behaviors, including number and type of sex partners (i.e. commercial, regular, non-regular, male, and female)
- Prevalence of HIV, syphilis, gonorrhea and chlamydia
- Drug and substance use (including needle/syringe sharing)
- Perception of HIV and STI transmission risk
- Exposure to HIV/AIDS prevention interventions

#### V. SAMPLE SIZES AND SAMPLING METHODS

#### 1. Sample sizes

Key indicators from the IBBS Round I were used to calculate sample sizes needed for target populations in Round II. Using design effects for cluster sampling, take-all sampling, and systematic random sampling in the IBBS II, sample sizes were calculated based on the following formula:

$$n = D * \frac{\left[ Z_{1-\alpha} \sqrt{2\overline{P}(1-\overline{P})} + Z_{1-\beta} \sqrt{P1(1-P1) + P2(1-P2)} \right]^2}{(P_2 - P_1)^2}$$

Where:

D = coefficient affecting the design

P<sub>1</sub> = estimated rate at the first survey time point

 $P_2$  = estimated rate at the next survey time point, (P2 - P1) is the magnitude of the determinable change

P = (P1 + P2)/2

 $Z_{1-a}$  = coefficient z corresponding to the desired level of significance

 $Z_{1-\beta}$  = coefficient z corresponding to the desired sampling efficiency

Indicators used for sample size calculation included HIV/STI prevalence and preventive or risk behaviors, such as needle/syringe sharing and condom use. Surveys in new provinces for Round II were considered initial investigations, and their basic indicators were made to match those of selected provinces from the Round I IBBS. Actual sample sizes for Round II are shown in Table 2 below. Please refer to *Appendix I* for further detail on sample size calculation.

Table 2: Actual sample sizes — IBBS round II, 2009

Provinces/cities	IDU	Venue-based (VSWs) FSW	Street-based (SSWs) FSW	MSM

#### 2. Sampling methods

The sampling methods used for this study were respondent-driven sampling (RDS) and time-location sampling (TLS) using two-stage cluster sampling. Take-all sampling (recruiting all eligible members of the target population) and systematic random sampling (recruiting every other eligible member of the target population) were used as alternative to TLS wherever the estimated size of a population was small. These alternative methods were only used for SSWs in Quang Ninh, Nghe An, Yen Bai and Can Tho and VSWs in Hai Phong, Quang Ninh, Da Nang, Yen Bai and Lao Cai. Chart 1 demonstrates sampling method selection using population characteristics. In order to ensure comparability between IBBS rounds, whichever sampling method, either RDS or TLS, was used in Round 1 was repeated in Round II.

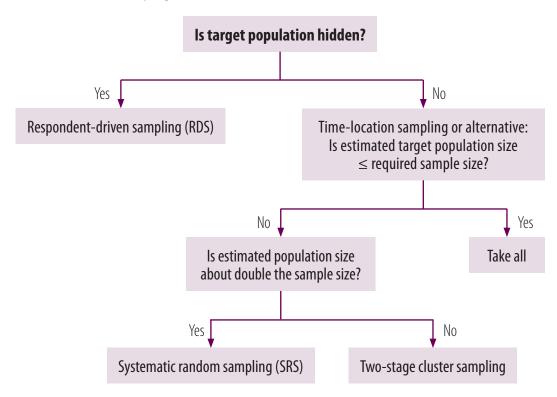

Chart 1: Determination of sampling methods for the IBBS Round II

RDS: Respondent-driven sampling

TLS: Time-location sampling

<sup>(\*):</sup> Take —all method

#### 2.1 Time - Location Sampling (TLS)

TLS use two stages sampling as follows:

- Stage I: Development of sampling frames and selection of clusters
- **Stage II:** Recruitment of study participants

#### **Stage 1:** Development of sampling frames and selection of clusters

The team developed maps for each province showing where eligible and potential participants could be reached. This took about two weeks per population at selected sites (see Table 1: Participant recruitment sites by MARP). A three-day training was provided in each province/city before mapping. The trainings covered how to identify and reach members of target groups, how to estimate and record the population size at each venue, and how to conduct interviews. Map developers were selected by provincial AIDS authorities and included staff from Departments of Health, Provincial Centers for Preventive Medicine, Provincial Centers for AIDS Prevention and Control, health workers at district/ward levels, social workers, and Women's and Youth Union staff.

Map developers went to their assigned geographic areas and identified all possible venues of target populations. They began by identifying initial venues through meetings with key informants, and then used the "snowball" technique to find other venues. At each venue, information on population size and how to reach targeted individuals was collected by rapid interviews with security guards, establishment owners, and neighbors, or through direct counting. Information on each venue was recorded in a form that included the address, special signs for identification purposes, and three estimates of the target population size: high, medium, and low.

Data were updated and computerized daily during the mapping process. The mapping ended when there were no new venues introduced or identified. All information on detected venues and on population size at each site was then put together to develop a sampling frame for each target population.

In some sites, there were substantial differences in the number of individuals available for survey, based on time of day the sites were surveyed. For example, the number of IDUs at one site was lowest at midday (average = 5) and highest in the morning (average = 10). A site like this was classified with two independent clusters in the sampling frame: morning and midday. This classification help to ensure inclusion of different kind of IDUs.

A cluster or primary sampling unit (PSU) was defined as a group of 10 individuals from a target population. Thirty clusters of each MARP group were randomly selected to achieve probability proportional to size. Venues with low numbers of the target population (e.g. two or three FSWs at each venue) were combined to create a cluster before being included in the sampling frame.

#### Stage 2: Recruitment of study participants at selected sites/venues

Recruiters were provided the addresses of venues and the specific number of individuals to be surveyed there from clusters that were randomly selected. During data collection, provincial supervisors visited selected sites accompanied by peer educators to identify and access eligible participants.

The study design allowed for more than one cluster to be recruited at a site. On a given survey visit, if there were more potential eligible subjects than the sample size required, participants were chosen at random. If not, all subjects present who satisfied the criteria were selected. If an insufficient number of participants were recruited on a given visit, study teams returned on other days and recruited participants until the requisite sample size was obtained.

All eligible participants were briefed on the study objectives and given invitation cards with information about the study, the addresses of data collection sites, and appointment dates. If a selected individual did not come into an appointment within two weeks, a recapture was made at the same site. If, after several rounds of recruiting, the desired sample size was not obtained, participants at nearby sites in the sampling frame were recruited. All replacement procedures were reviewed and approved by NIHE in consultation with local staff.

#### 2.2. Take-all sampling

After mapping, if the population size estimate was smaller than required, the *take-all* method was used, in which all members of the target population at all mapped locations were recruited. Study teams visited designated sites, met eligible participants with the help of peer educators, explained the study objectives, and distributed invitation cards (as above).

#### 2.3. Systematic random sampling

After mapping, if the population size estimate was approximately twice the required sample size, *systematic random sampling* was applied. The study team visited all mapped locations and selected one in two eligible individuals. In cases where the sample size was not obtained after all sites were visited, this procedure was repeated until the sample size was obtained.

#### 2.4. Respondent-driven sampling (RDS)

RDS is a chain-referral method in which recruitment is achieved through participant referral. However, unlike the "snowball" method, it gives unbiased estimates of population parameters (Heckathorn 1997). This method was used for IDUs in Ha Noi, Da Nang, HCMC and Can Tho, and for all MSM populations.

RDS was initiated by recruiting participants identified as "seeds". Seeds were selectively chosen to obtain diversity of the target population characteristics, geographic area, and large networks of target populations. Study investigators selected seeds who were

introduced by local staff. Seeds were interviewed as participants and given a limited number of referral coupons (2 or 3) and asked to invite peers from within their social network to participate, which means peers who they knew by name and who knew them. Subsequent participants who completed the interviews were given additional coupons to invite additional peers from their social network. This process continued until sample size was reached, which usually required five to eight waves, or rounds, of referrals. The number of coupons was reduced to one and subsequently zero as the participant number neared the target sample size.

Each referral card was uniquely coded in order to link recruiters to their recruits for appropriate data adjustment in the analysis and for managing reimbursement for successful recruitment of peers. Receptionists at data collection centers were trained on the management of referral cards and coding.

#### VI. DATA COLLECTION

#### 1. Research team

#### 1.1. TLS recruiters

The field study team that recruited participants using TLS included staff who took part in site mapping and had experience in community outreach. These included outreach workers and peer educators from community-based interventions.

#### 1.2. Interviewers

Staff from district/ward health centers, provincial Preventive Medicine Centers, provincial AIDS Prevention and Control Centers, and social workers were selected to conduct interviews.

#### 1.3. Laboratory staff

The research team assigned laboratory staff from provincial Centers for Preventive Medicine and provincial Centers for AIDS Prevention and Control to collect biological samples. Counselors in charge of pre- and post-test counseling also assisted with specimen collection.

#### 1.4. Training of staff

A four day training was held in each province prior to data collection. The course covered HIV/AIDS and risk behaviors, study design, interview skills, use of the questionnaire, how to access target populations, data and specimen handling and transfer, and monitoring and supervision of data collection. Interviewers conducted role-plays and discussions with peer educators currently delivering intervention services in target sites. NIHE laboratory technicians trained laboratory staff on specimen collection, storage, and testing procedures based on the National Guidelines for HIV and STI testing.

#### 2. Study centers and data collection

Data colletion ran from June 2009 to February 2010 for all 12 provinces. Study centers were set up for collection of biological specimens and behavioral data. Each study location had separate sites for different target populations. Sites were selected based on:

- Geographic convenience for target populations. If a locale was large (e.g. HCMC), data collection sites were located conveniently near common venues for participants.
- **Sufficient rooms for reception, interviews, and specimen collection.** Teams considered privacy, security, and respect for participants in site selection.
- Electricity, running water and toilet
- Accessibility

Each data collection center had three separate areas: a reception area, an interview room, and a room for collection of biological samples with a space for individual counseling.

Eligible participants were registered at the reception desk on arrival. The receptionist conducted primary screening of these individuals by asking questions according to the criteria for subject selection. Participants who did not meet the criteria were excluded from the survey, as were those who had already participated. The receptionist then read and provided an informed consent form to qualifying participants, answered any questions or concerns, and signed the consent form along with a witness.

After registration, qualified participants were ushered to a private interview room. Before each interview, the investigator checked to see that the individual met the selection criteria. Interviewers conducted individual interviews using structured questionnaires and assisted participants to understand the questions as required. Each interview lasted about 30-45 minutes.

After the interview, participants were guided to a room for pre-test counseling and collection of biological samples. Similar to the interview rooms, testing rooms were arranged to ensure participant privacy and security. Lab technicians (one for each center) collected biological specimens of blood, urine and/or rectal swabs. Participants were given a test tube and instructed how to collect urine samples for gonorrhea and chlamydia testing.

Subjects' ID numbers were checked regularly at each step to ensure that those on questionnaires and specimen test tubes matched. Before subjects left the premises, receptionists rechecked all steps and associated data/specimens to ensure the process was completed correctly.

All specimens were stored at 40C - 80C in study center and during daily transportation to the HIV lab in Provincial AIDS center. HIV tests have been conducted in this lab and gave result in two weeks. All the leftover of specimen were stored at -200C to -800C until transported to NIHE.

All participants were compensated for their time and traveling expenses with VND 50,000-100,000, equivalent to US\$3.00-5.00, based on individual locales. RDS participants received additional incentives (secondary incentive) for recruiting their peers to participate in the study.

Data collection were conducted from June 2009 - Feb 2010 in all 12 city/provinces

#### VII. QUALITY ASSURANCE AND SUPERVISION

National technical staff from NIHE, FHI, UNODC and US CDC were responsible for training provincial staff on data collection and for providing direction and technical support during the survey. Technical staff from NIHE, HCMC Pasteur Institute, and the Tay Nguyen Institute of Hygiene and Epidemiology monitored field deployment. Staff from provincial Centers for AIDS Prevention and Control also provided supervision. Supervisors worked together on mapping, recruiting participants according to the sampling frame, interviewing, and clinical specimen collection at study sites. All significant issues which arose were managed by national supervisors with TA from FHI and US CDC.

#### VIII. DATA MANAGEMENT AND ANALYSIS

#### 1. Data entry and cleaning

Raw data were converted to STATA format for data analysis and it took roughly two months to enter and clean the data. An independent data entry group entered the data into an EpiData database developed and maintained by NIHE. Double data entry was performed on 25% of the records as data entry took place to identify incorrect entries. If inconsistency was found in over 10% of the double data entries, an additional 25% of the records were then randomly selected to be reviewed through a second entry.

Variable names applied in the datasets in Round II were matched to those in Round I. Upon data entry completion, all datasets were analyzed for validity and logical flow between the questions, and errors were checked directly against the questionnaires.

#### 2. Data analysis

#### 2.1. Time-location sampling

STATA 10.0 was used for analysis of TLS samples. For designs using two-stage cluster sampling, weighting was applied to adjust for different sampling probabilities among participants. In cluster sampling, differences in attendance patterns at the sampled venues introduced clustering of people with common characteristics and different sampling probabilities, and weighting adjusted for these biases. Although the two-stage cluster sampling method had been designed to obtain self-weighted samples by creating clusters with the same number of individuals (10), the actual number of recruitments in each cluster varied, both over and under 10, resulting in different probabilities of each person to be selected into the sample. A detailed review of data weighting is presented in *Appendix 2*.

#### 2.2. Respondent-driven sampling

In order to obtain estimates that are representative of the study population such as HIV prevalence, data from samples obtained through RDS must be analyzed using RDS Analysis Tool (RDSAT). This tool was developed specifically to compute weights using recruitment patterns and network sizes, and these weights adjust the sample population proportions to provide unbiased estimates that can be generalized to the larger population of interest. IBBS RDS data were first analyzed using RDSAT. However, the adjusted estimates for several key indicators were questionable, and most concerning was HIV prevalence among IDUs in Ha Noi. In the sampled Ha Noi IDUs population, 20.7% were HIV-infected. The adjusted HIV prevalence obtained in RDSAT was significantly lower at 11.5%. In addition, the resulting MSM population recruited in HCMC consisted of a large proportion (approximately 40%) who reported selling sex in both the 2006 and 2009 IBBS rounds. The MSM sample population in HCMC does not appear to have engaged random recruitment, or recruited a larger proportion of the MSM subpopulation with higher risk than is truly present in the general MSM population.

The IBBS study investigators have been working with statisticians and RDS experts to determine the most appropriate approach for analyzing IBBS data sampled with RDS. This included exploring RDS theories and assumptions that are not applicable in the Vietnam context, analyzing subpopulations within the sample populations, and applying different models and statistical analysis software. This work is ongoing and may result in estimates different from both the sample population proportions and RDSAT adjusted estimates. For the interim period, the study investigators are providing unweighted sample population proportions in this report. The reported results should be interpreted not as representing the general IDUs or MSM population, but as estimates for the populations of IDUs sampled in Ha Noi, Da Nang, HCMC, Can Tho and of MSM sampled in Ha Noi, Hai Phong, HCMC, and Can Tho.

#### 3. Testing techniques

#### 3.1. HIV testing

HIV testing was performed using MOH Algorithm III, with two enzyme-linked immunosorbent assay (ELISA) tests and one rapid test using immunochromatography. HIV testing was performed at standardized HIV labs accredited for HIV-positive confirmation. Ten percent of negative samples and five percent of positive samples were randomly selected and retested for quality assurance at the National Reference HIV Laboratory at NIHE. Equivalent MOH algorithm is presented in Appendices 3 and 4.

#### 3.2. Syphilis testing

Syphilis serologic testing was performed on serum samples using a rapid plasma regain (RPR) screening test and a treponema pallidium hemaglutination assay (TPHA) confirmation. A syphilis case was laboratory confirmed and treated when the serum sample was positive using both techniques. See appendix 3.

#### 3.3. N. gonorrhea and C. trachomatis testing

*N. gonhorhea* and *C. trachomatis* tests were performed using polymerase chain reaction (PCR). Specimens included urine from FSWs and MSM and rectal swabs from MSM. They were collected at study centers and stored at -20°C in laboratories at the provincial Preventive Medicine Center or HIV/AIDS Prevention and Control Center. All were then transported to the laboratory at NIHE and tested according to the manufacturer's directions.

Individuals who returned for their results and were positive with HIV or syphilis were offered or introduced to relevant care services. These included free treatment for syphilis and/or transfer to HIV care and support services. Pre- and post-test counseling proceeded as follows:

- Prior to testing, all participants received pre-test counseling. Additional counseling was available for those who requested it.
- The pre-test counseling sheet was signed by the counselor, appended to the consent form, and stored with the other documents or records.
- All participants were given an appointment card to return for HIV and syphilis results at the study center, which became available within two weeks of participation in the study. The appointment card contained the details of the counseling service center (address, telephone number and hours of business) and the address and telephone number(s) of the local supervisor(s) in case of any problems.

Trained counselors delivered the results verbally in person (never in writing or by telephone). No HIV status certificates or any other form of written results were given, and counselors provided individually appropriate counseling with each result. To receive their results, participants came in individually with their original appointment card. No results were given without this original card.

#### IX. ETHICAL CONSIDERATIONS

Participation of respondents in the study was strictly voluntary. Training for field staff emphasized the importance of obtaining signed, informed consent and maintaining complete confidentiality. Names and addresses of participants were not recorded.

The Ethics Review Board of NIHE, the Vietnamese MOH, the FHI Protection of Human Subjects Committee, and the CDC Internal Review Board jointly approved the study protocol, questionnaires, and consent forms obtained from the target groups.

The following general procedures were conducted to protect participants who may be vulnerable to societal pressures, coercion and control measures.

Field staff held discussions with employers (such as bar and karaoke owners) to clarify the purposes of the study and the regulations. No personal identifiable information on participants was recorded or provided to employers, and participation of all individuals was completely voluntary. Interviewers were not involved in any way with the recruitment of participants.

- Non-governmental organizations (NGOs) provided study populations with information on the study prior to recruitment by working with specific groups, educational sessions at worksites, or peer-to-peer contacts. During these sessions, facilitators clarified the purpose of the study and answered questions clearly and directly.
- Prior to recruitment, research staff explained all procedures in detail to participants and answered their questions. Interviewers emphasized that should participants decide to withdraw from the study, their decision would not affect any services they were provided by agencies or clinics. A research staff member and a witness both signed the consent forms.
- The study was anonymous. No names or personal identifiers were recorded. All questionnaires and biological specimens were labeled with a unique ID number. Participants were given an appointment card with their unique ID number to identify them when they returned for results, counseling, and free STI treatment. Because there were no personal identifiers, it was impossible to trace positive results or to determine who participated in the study. Participants were asked to come at a specified appointment time with their appointment card to receive their results.
- Provincial and national staff closely monitored the implementation and completion of the consent procedures.

## Results and discussion

## I. DEMOGRAPHIC AND SOCIOLOGICAL CHARACTERISTICS OF STUDY POPULATIONS

The following are the main results. The details are presented in appendices.

#### 1. Injecting drug users (IDUs)

Characteristics of IDUs for Round II are presented in *Table 4*. The mean age of IDUs surveyed was (25 years) in Da Nang to (36 years) in Lao Cai and Hai Phong. One-third of IDUs in HCMC were younger than 25 years old.

Unemployment or employment in low-income/unstable jobs among IDUs in all provinces was high: from 70 to 80% (*Appendix 5*). The median monthly income among this population was between 1-2.5 million VND.

Most IDUs in provinces surveyed had been *using* drugs for over 8 years. This could represent a population that has a survival bias and thus highlights the need to look closely at populations injecting for less than 1 year. The overwhelming majority of IDUs had been injecting drugs for over a year (from 73% in Da Nang to 96% in Quang Ninh). Provinces with a higher percentage of new injecting drug users (those who began using within a year of the survey) were Nghe An (16%), Da Nang (27%), Dong Nai (23%) and An Giang (20%).

In most provinces, at least one-third of IDUs surveyed had been to a governmental drug rehabilitation center, also known as an 06 center. Percentages ranged from 16% in Nghe An to 47% in Lao Cai.

In comparing IDUs populations from 2006 and 2009, the percentage of those who had ever been in an 06 center was much higher in Round II. The proportion changed from 31% to 47% in Ha Noi (p<0.05), 26% to 37% in Hai Phong (p<0.05), and 24% to 36% in HCMC (p<0.05). In HCMC, the number of IDUs who were released from 06 centers increased dramatically between 2006 and 2009. The HCMC Department of Social Evils Prevention and Control reports that over 35,000 drug users left HCMC 06 centers between 2006 and the close of 2008, and another 20,000 were released in 2009. This increase may have had a significant influence on the IBBS Round II epidemiological data in HCMC, as discussed below.

Table 4: Characteristics of IDUs - IBBS 2009

#### 2. Female sex workers (FSWs)

Some demographics differed between street-based sex workers (SSWs) and venue-based sex workers (VSWs). SSWs were in general older than VSWs, had sold sex for longer, and had lower income (although direct income from selling sex was higher at some sites).

The mean age of SSWs ranged from 25 years (Nghe An and Dong Nai) to 36 years in Da Nang, and for VSWs from 24 years (Nghe An) to 30 years (Ha Noi and Da Nang). Most SSWs in large cities such as Ha Noi, Hai Phong, Da Nang, HCMC, Can Tho, An Giang were over 30 years old (51%–73%), whereas the majority of VSWs were under 30 (>50%).

The majority of FSWs had sold sex for more than three years, which is compatible with results from the 2006 IBBS. Data in Table 5 show that although classified as street-based, SSWs in Quang Ninh, Nghe An, Yen Bai, and Dong Nai most commonly waited for clients in bars and karaoke venues, indicating movement off the streets to avoid police round ups. Over 85% of self-identified SSWs in Quang Ninh, Yen Bai, Dong Nai and An Giang reported that their most common waiting points for clients were in bars or karaoke venues.

#### 3. Men who have sex with men (MSM)

Most MSM surveyed in Round II were between 20 to 30 years old. Those who had received money for sex in the past month (MSW) tended to be about two years younger than those who had not, with the exception of Hai Phong. The age stratification is significantly different between the IBBS rounds, with the younger age group 20-25 fewer in 2009 (25%) than in 2006 (60%), which may have resulted from sampling issues (see section VIII.2.2 for a discussion on these issues). MSM participants in Round II also had relatively low income, averaging less than three million VND per month. It is not possible to compare average income between respondents from the Two IBBS round because income ranges, as opposed to specifie amounts, were collected in 2006. MSM has higher income in 2009. This may inflation, however, rather than characteristic differences between the two differences study rounds.

Except in Hai Phong, men who had not sold sex had stronger preferences for sex with other men than their MSW counterparts. In Hai Phong, both groups preferred sex with men exclusively or preferred to have sex with men versus women, at a combined proportion of over 80%, and no one reported preference for sex with only women. About one-third to one-half of MSM respondents preferred to have sex exclusively with men. However, a much lower proportion (13%) of Ha Noi MSW had a preference for only male sexual partners. The population with the largest proportion preferring only women as sex partners was MSW in Can Tho.

Table 5: Characteristics of street-based sex workers - IBBS 2009

#### II. HIV AND STI PREVALENCE AMONG TARGET POPULATIONS

#### 1. Injecting drug users

HIV prevalence among IDUs was high in many provinces surveyed in Round II, including Dien Bien (56%), Quang Ninh (56%), Hai Phong (48%), and HCMC (46%). It was also relatively high in Ha Noi (21%), Lao Cai (22%), Dong Nai and Nghe An (both 24%). Da Nang had the lowest prevalence among IDUs, at only 1%. Syphilis prevalence was low in all provinces surveyed (less than 2%).

**Figure 1:** HIV and syphilis prevalence among IDUs — IBBS 2009

A number of provinces had lower HIV prevalence among IDUs in Round II versus Round I. These included Hai Phong (48% vs. 66%, p<0.05), Can Tho (32% vs. 44%, p<0.05), and Ha Noi (21% vs. 24%, p>0.05) in 2009 v.s. 2006, respectively. However, HIV prevalence among IDUs in HCMC in 2009 was higher than in 2006 (46% vs. 34%, p<0.05) respectively). It is important to note a few developments in HCMC during the period between the two surveys when considering this change:

- Between 2006 and 2008, approximately 20,000 drug users returned to their communities from 06 centers in HCMC (see Figure 3).
- In Round I, 23% of IDUs surveyed had been at a drug rehabilitation center (06 center).
   The proportion climbed to 36% in Round II.
- Over 50% of IDUs surveyed in 2009 who had been in a 06 center were HIV-positive. We have no data in 2007, 2008 (see Figure 4).
- There were fewer new IDU<sup>2</sup> in 2009 (12.5%) than in 2006 (25.7%, p<0.05) (see *Table 4*). The percentage of new IDUs who were HIV-positive in 2009 (18%) was significantly lower than in 2006 (29%).

32

<sup>2</sup> 

These statistics suggest the possibility that the higher prevalence in 2009 may be due, in part, to a significant number of HIV-infected individuals returning from 06 centers between 2006 and 2009.

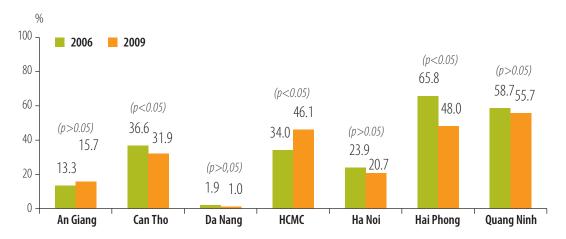

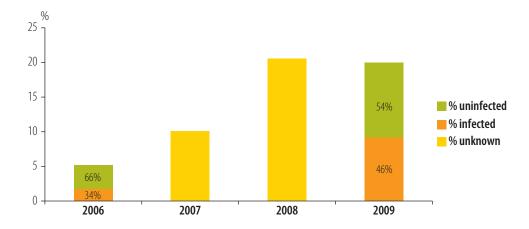

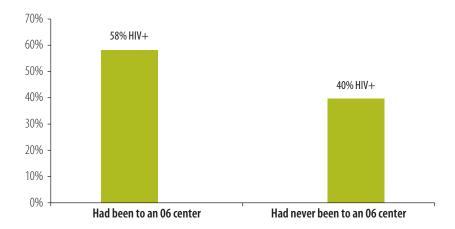

Figure 2: Comparison of HIV prevalence among IDUs - IBBS 2006 and 2009

**Figure 3:** Cumulative number of individuals in HCMC returning to the community from drug rehabilitation centers (06 centers) and proportion HIV-positive between 2006 and 2009

**Figure 4:** HIV prevalence among IDUs — by status of having ever been in an drug rehabilitation center (06 center) in HCMC, 2009

#### 2. Female sex workers

HIV prevalence among FSWs was highest in Ha Noi, Hai Phong, HCMC and Can Tho (>15%). Provinces with prevalence rates in the middle range were Lao Cai, Yen Bai and An Giang. HIV prevalence was lowest in Quang Ninh, Nghe An and Da Nang (<3%). SSWs in Hai Phong had the highest prevalence at 23%. In general, SSWs had higher HIV prevalence than VSWs.

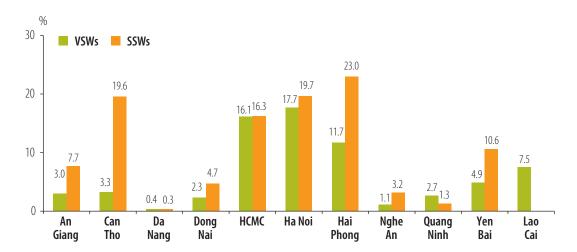

Figure 5: HIV prevalence among VSWs and SSWs - IBBS 2009

Compared to 2006 IBBS, HIV prevalence among VSWs was higher in 2009 in Ha Noi, Hai Phong and HCMC. HIV prevalence was lower for the remaining provinces surveyed, with the greatest difference in An Giang where it dropped from 11% in 2006 to 3% in 2009 (Figure 6).

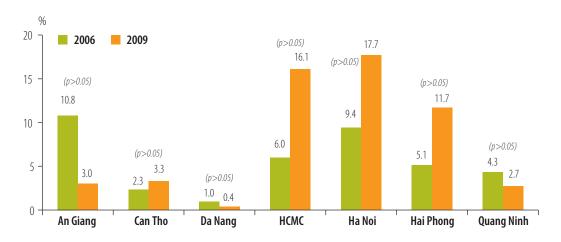

Figure 6: HIV prevalence among venue-based sex workers — IBBS 2006 and 2009

Among SSWs, HIV prevalence appears to have stabilized or dropped in Ha Noi, Quang Ninh, Da Nang and Can Tho. However, data for Hai Phong are more concerning, showing a change from 7% in 2006 to 23% in 2009. Data for SSWs in HCMC and An Giang also suggest increasing prevalence (Figure 7).

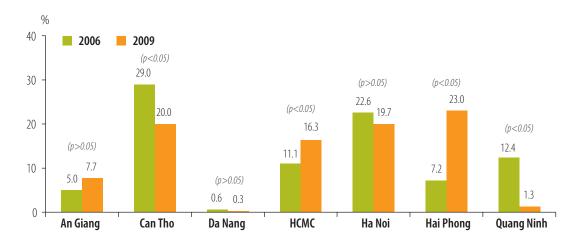

Figure 7: HIV prevalence (%) among street-based sex workers — IBBS 2006 and 2009

IBBS results show that SSW and VSW STI prevalences differ in some provinces. While STI prevalence appears to have decreased between 2006 and 2009 for both SSWs and VSWs in Ha Noi, Chlamydia prevalence appears to have increased for SSWs in HCMC (10% in 2009 compared to 6% in 2006). Gonorrhea prevalence was low and relatively rare in both cities. Syphilis prevalence remained low among FSWs, at less than 2% in most provinces surveyed (except Can Tho, An Giang).

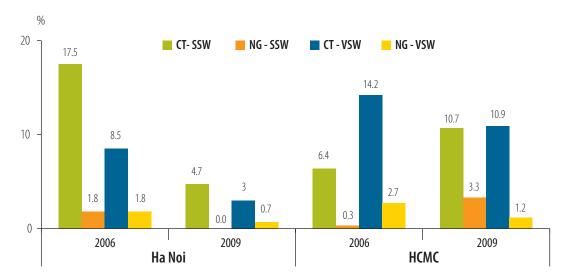

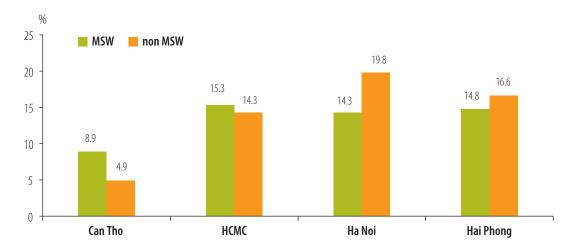

Figure 8: Chlamydia (CT) and Gonnorhea (NG) prevalence among VSWs and SSWs in Ha Noi and HCMC - IBBS 2006 and 2009

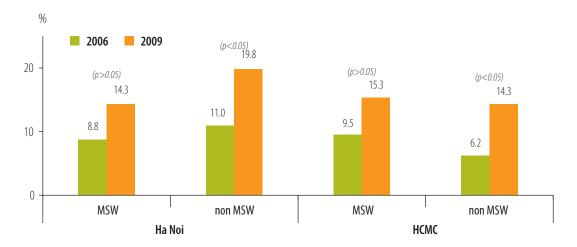

#### 3. Men who have sex with men

HIV prevalence among MSM in Round II was over 10% in all provinces surveyed, except of Can Tho, and it was as high as 20% among MSM who had not sold sex in Ha Noi.

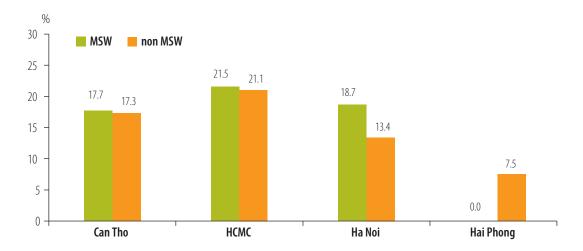

**Figure 9:** HIV prevalence among MSM had sold sex (MSW) and MSM had not sold sex (non MSW) — IBBS 2009

In Ha Noi and HCMC, HIV prevalence among both groups of MSM in 2009 was significantly higher than in 2006. For MSM who had sold sex (MSW) in Ha Noi, prevalence was 14%, versus 9% in 2006 in Ha Noi. For those who had not sold sex (non MSW), the prevalence was 20% in 2009, versus 11% in 2006. Data for HCMC were similar.

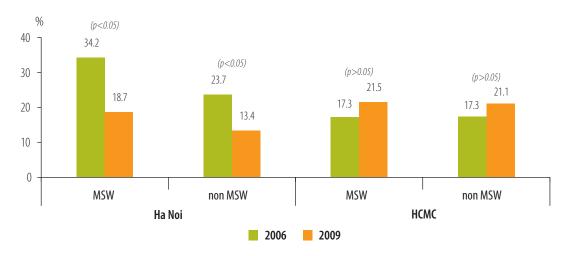

**Figure 10:** HIV prevalence among MSM had sold sex (MSW) and MSM had not sold sex (non MSW) — IBBS 2006 and 2009

Sexually-transmitted infection (STI) prevalence (other than HIV) among MSM was high. One in five MSM in HCMC was infected with at least one of the following STIs: syphilis, genital gonorrhea, rectal gonorrhea, genital Chlamydia, or rectal Chlamydia.

**Figure 11:** STI prevalence among MSM had sold sex (MSW) and MSM had not sold sex (non MSW) – IBBS 2009

Unlike in Ha Noi, a slightly higher proportion of MSM in HCMC were infected in 2009 than 2006. STI infections among Ha Noi MSM did decline in large proportions, but prevalence was still high at over 10%.

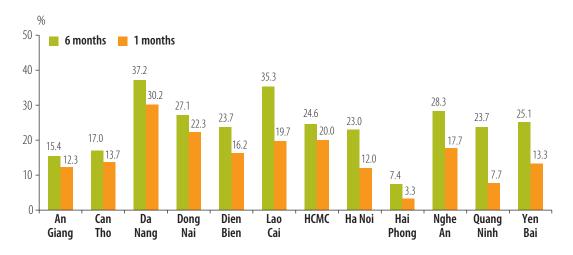

**Figure 12:** STI prevalence among MSM had sold sex (MSW) and MSM had not sold sex (non MSW) in Ha Noi and HCMC — IBBS 2006 and 2009

#### III. HIV/STI BEHAVIORAL INDICATORS AMONG TARGET POPULATIONS

# 1. Injecting drug users

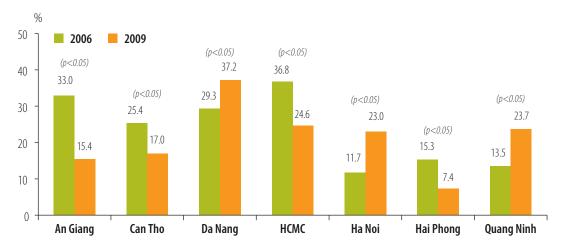

The following are key findings of risk behaviors among IDUs, including injecting and sexual risk behaviors. More data on IDUs are available in Appendix 5.

Figure 13 illustrates the percentage of needle and syringe sharing among IDUs in 2009 in the last six months and last one month. Needle and syringe sharing in the last six months was relatively high (15% to 37%) in all provinces surveyed but Hai Phong (7%). Reported sharing in the last six months was highest in Da Nang and Lao Cai

**Figure 13:** Proportion of IDUs reporting needle and syringe sharing — IBBS 2009

In comparing data from Rounds I and II, needle sharing in the last six months among IDUs in 2009 was lower in Hai Phong, HCMC, Can Tho, and An Giang. Conversely, needle sharing was higher in Ha Noi, Da Nang and Quang Ninh.

**Figure 14:** Proportion of IDUs reporting needle and syringe sharing in the last six months — IBBS 2006 and 2009

Figure 15 shows a high percentage of HIV-positive IDUs who reported ever having shared needles. Reported sharing was highest in Quang Ninh where 82% of HIV-positive IDUs reported ever having shared a needle.

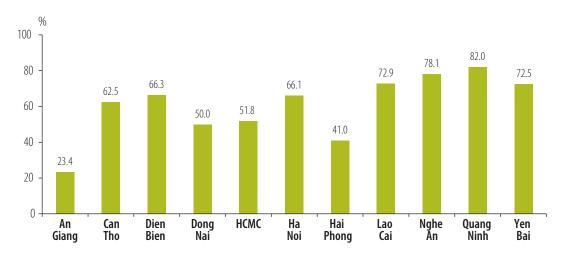

Figure 15: Proportion of HIV-positive IDUs who ever shared needles — IBBS 2009

In all provinces surveyed, with the exception of Hai Phong, at least 40% of IDUs reported sexual activity with a regular partner in the last 12 months. In addition to having sex with regular partners, a portion of IDUs in every province reported having sex at least once with a sex worker in the last 12 months (from 10% in Dien Bien, Quang Ninh, Dong Nai to 45% in Da Nang).

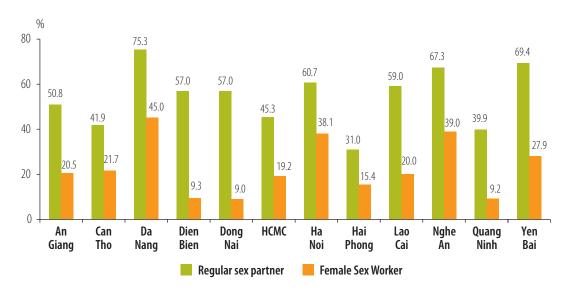

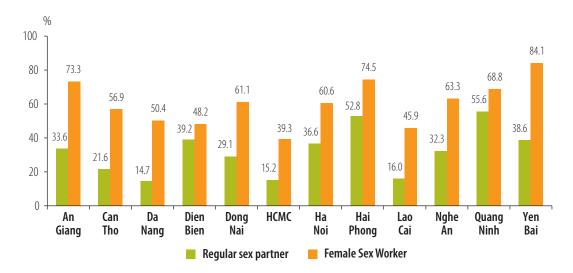

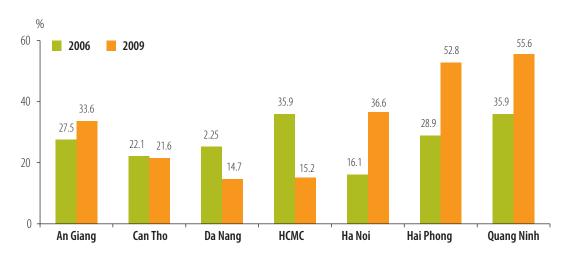

Figure 16: Proportion of IDUs who had sex by type of partner in the last 12 months — IBBS 2009

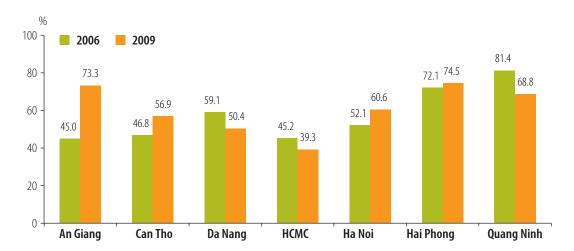

**Figure 17:** Proportion of IDUs who reported consistent condom use by type of partner in the past 12 months — IBBS 2009

Consistent condom use in the past 12 month among IDUs with regular partners (wives and girlfriends) varied, from 15% in Da Nang to 56% in Quang Ninh. While consistent condom use with sex workers was higher than with regular partners, from 39% in HCMC to 84% in Yen Bai, it was still low in provinces surveyed. Compared to the 2006 results, a greater proportion of IDUs reported consistent condom use with their regular sex partners in most provinces, specifically Ha Noi, Hai Phong, Quang Ninh, and An Giang. The reverse is true for Da Nang and HCMC, where the proportions dropped from 25% and 36%, respectively, to 15%.

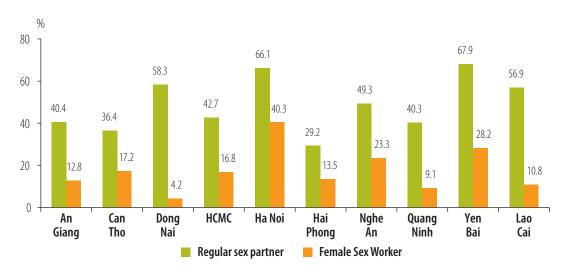

**Figure 18a:** Proportion of IDUs who reported consistent condom use in the last 12 months with regular partners— IBBS 2006 and 2009

Sexual risk practices with sex workers among IDUs appear to have changed little, with the exception of An Giang, where consistent condom use changed from 45% to 73%, and Quang Ninh, which decreased from 81% to 69% (Figure 18b).

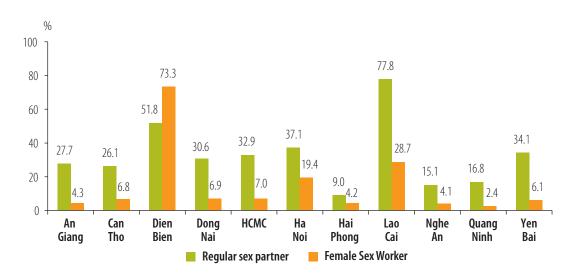

**Figure 18b:** Proportion of IDUs who reported consistent condom use in the last 12 months with FSWs – IBBS 2006 and 2009

Round II data show that a significant proportion of HIV-positive IDUs are sexually active. Thirty to 68% of HIV-positive IDUs reported that they had had sex with their regular partners in the past year. Yen Bai was of particular concern (Figure 19). While 57% of HIV-positive IDUs in Lao Cai reported having had sex with regular partners, the province had one of the lowest reported consistent condom use rates among IDUs with regular partners, at 16% (Figure 17). Almost half of the HIV-positive IDUs in Ha Noi mean while reported sexual activity with sex workers.

**Figure 19:** Proportion of HIV-positive IDUs who reported having had sex in the last 12 months by partner type — IBBS 2009

Consistent condom use within the past year among HIV-positive IDUs varied considerably by province. Roughly one-third of HIV-positive IDUs surveyed in 2009 had had regular sex partners and reported that they did not consistently use condoms during sex. Over 50% of HIV-positive IDUs in Lao Cai and Dien Bien reported inconsistent condom use with their regular partners, Lao Cai at an alarming 78%. HIV-positive IDUs reported more consistent condom use with FSWs, but data from certain areas including Dien Bien, Lao Cai and Ha Noi showed considerable need for targeted prevention messaging for this group (Figure 20).

**Figure 20:** Proportion of HIV-positive IDUs who had had unprotected sex by partner type in the last 12 months — IBBS 2009<sup>3</sup>

#### 2. Female sex workers

The following are the main behavioral indicators on female sex workers (FSWs) including sexual and injecting behaviors. More detailed data are presented in Appendix 6.

Client frequency varied considerably among FSWs in surveyed provinces. FSWs in provinces such as Hai Phong, Nghe An, and Dong Nai averaged significantly more clients than other provinces, at more than 10 clients per week. SSWs in Nghe An averaged the highest number of clients per week, at 24. FSWs in other provinces averaged closer to five clients per week. A comparison of data from 2006 and 2009 shows that client frequency increased slightly in most provinces for both VSWs and SSWs.

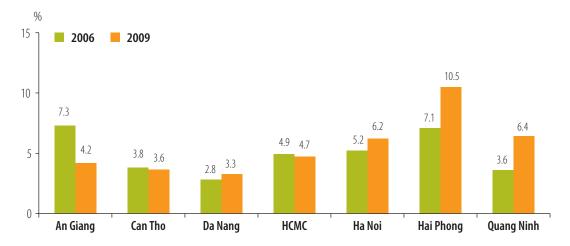

Figure 21a: Average number of clients in the last week per VSWs — IBBS 2006 and 2009

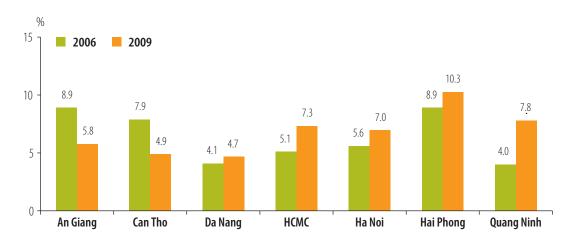

Figure 21b: Average number of clients in the last week per SSWs – IBBS 2006 and 2009

While condom use with regular *clients* at last sex among FSWs was reportedly high in most provinces, consistent condom use in the last month varied considerably, and was particularly low in Ha Noi, HCMC and Dong Nai. FSWs reported using condoms more consistently with one-time clients than with regular clients.

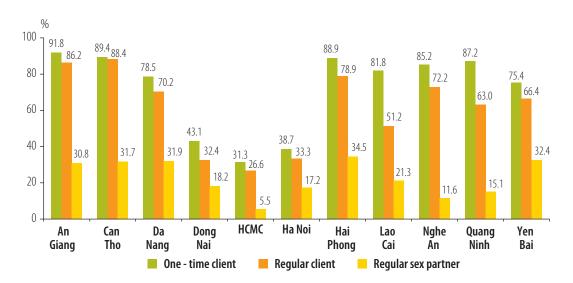

Figure 22a: Consistent condom use in the last month among SSWs by sex partner type — IBBS 2009

Consistent condom use with regular partners in the last month was low in all provinces for both VSWs and SSWs. Provinces with the lowest reported consistent condom use with regular partners among SSWs included Ha Noi, Quang Ninh, HCMC, Nghe An and Dong Nai (under 20%). Provinces with the lowest reported condom use with regular partners among VSWs included and Ha Noi, HCMC, Can Tho, Nghe An and Dong Nai (under 20%).

In general, consistent condom use did not vary considerably between SSWs and VSWs, with the exception of Dong Nai. Consistent condom use in the last month among SSWs in Dong Nai was twice as high as that of VSWs (39% vs. 21%).

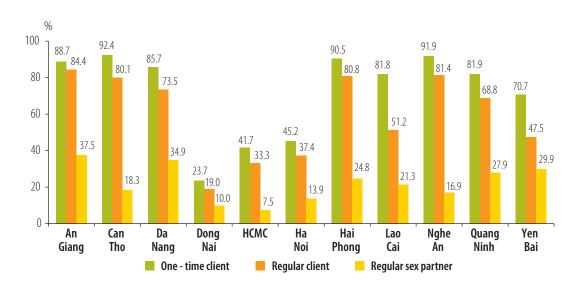

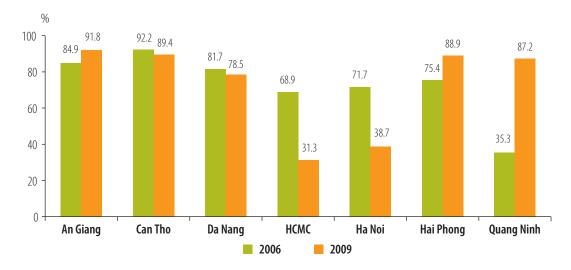

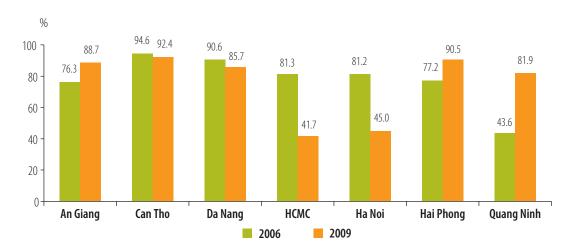

Figure 22b: Consistent condom use in the last month among VSWs by sex partner type — IBBS 2009

A comparison of data on consistent condom use from Rounds I and II shows variation among provinces. Provinces with more consistent condom use were An Giang, Hai Phong, and particularly Quang Ninh, where consistent condom use in the last month with one-time clients more than doubled for SSWs from 35% to87% (p<0.05), and nearly with regular clients (34.8% to 69%, p<0.05).

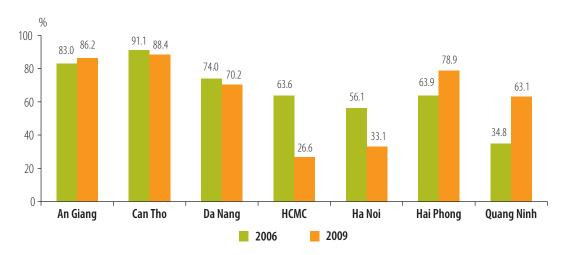

Conversely, data from Ha Noi and HCMC are cause for concern. For both SSWs and VSWs, consistent condom use appears to have dropped considerably both for one-time and regular clients. In HCMC, consistent condom use among SSWs more than halved dropping from 69% to 31% (p<0.05) for one-time clients (Figure 23a), and 64% to 27% (p<0.05) for regular clients (Figure 24a). Among VSWs it dropped from 81% to 42% (p<0.05) for one-time clients (Figure 23b), and 72% to 33% (p<0.05) for regular clients (Figure 24b).

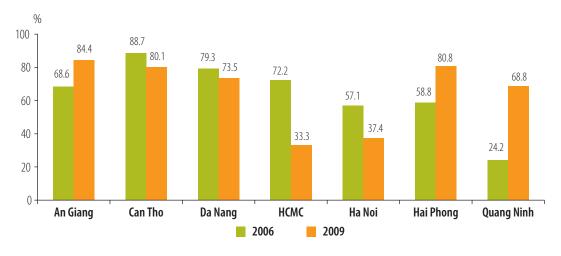

**Figure 23a:** Consistent condom use in the last month with one-time clients among SSWs — IBBS 2006 and 2009

**Figure 23b:** Consistent condom use in the last month with one-time clients among VSWs — IBBS 2006 and 2009

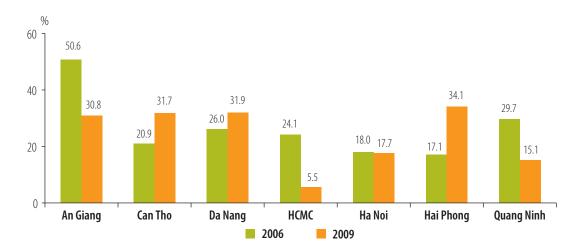

**Figure 24a:** Consistent condom use in the last month with regular clients among SSWs — IBBS 2006 and 2009

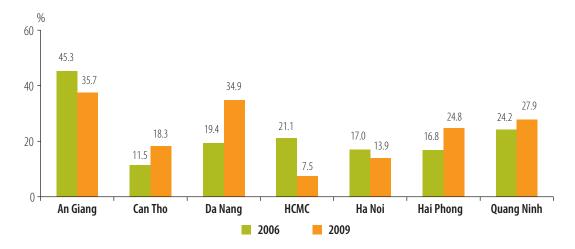

**Figure 24b:** Consistent condom use in the last month with regular clients among VSWs — IBBS 2006 and 2009

Consistent condom use in the last month with regular partners was low for both Rounds I and II. However, some provinces saw notable increases, including Hai Phong, Da Nang, and Can Tho. Provinces with considerable decreases in consistent condom use with regular partners among SSWs included Quang Ninh, HCMC and An Giang, the most concerning being HCMC, with a decrease from 24% to less than 6% (p<0.05). Ha Noi, HCMC and An Giang showed decreases in consistent condom use with regular partners among VSWs as well (Figure 25a, 25b).

**Figure 25a:** Consistent condom use in the last month with regular partners among SSWs — IBBS 2006 and 2009

**Figure 25b:** Consistent condom use in the last month with regular partners among VSWs — IBBS 2006 and 2009

Figure 26 shows the percentage of surveyed FSWs who have ever used drugs. Drug use among FSWs is generally much higher in urban hubs and ports, city, like Ha Noi, Hai Phong, HCMC and Can Tho, especially among SSWs. SSWs generally report more drug use than VSWs.

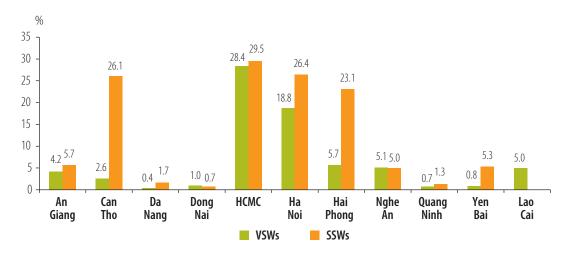

Figure 26: Ever used drugs among FSWs — IBBS 2009

Drug injection is also remarkably high in the provinces where reported drug use is also high (Ha Noi, Hai Phong, HCMC, Can Tho). In these provinces, the majority of FSWs who use drugs also inject. SSWs were much more likely to report drug injection than were VSWs.

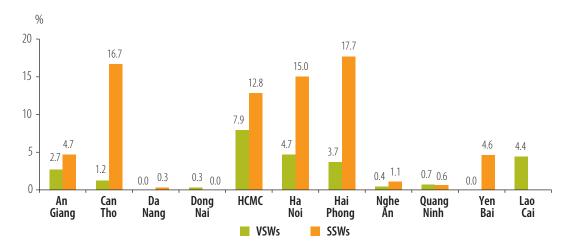

Figure 27: Proportion of FSWs who had ever injected drugs — IBBS 2009

Drug injection among SSWs appears to have increased substantially in Hai Phong and HCMC between 2006 and 2009, where the proportion in each province more than doubled. Drug injection appears to have stabilized or reduced for the other provinces surveyed in both IBBS rounds.

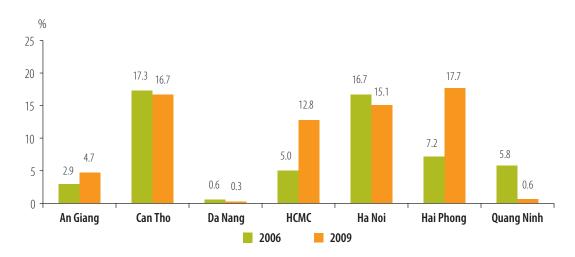

Figure 28a: Drug injection among SSWs — IBBS 2006 and 2009

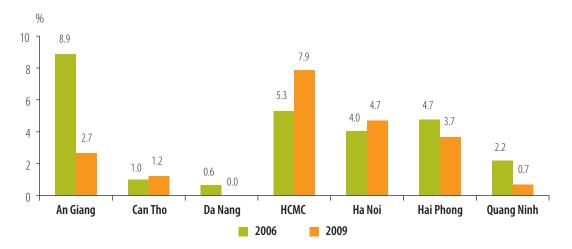

Figure 28b: Drug injection among VSWs – IBBS 2006 and 2009

Drug injection thus remains a critical risk factor for HIV transmission among FSWs. HIV prevalence for FSWs who injected drugs was higher than those who did not inject drugs in all provinces surveyed. Prevalence was especially high among FSWs who injected in Can Tho, HCMC, Lao Cai, Hai Phong, and Ha Noi. In Can Tho, the difference was stark; 78% of SSWs who inject were HIV-positive versus 8% for those who did not. SSWs and VSWs who injected in HCMC also had comparably high prevalences at 49% and 54%, versus 11% and 14% for those who did not inject. Injecting FSWs prevalence figures were equal to or higher than those of male IDUs in the same provinces.

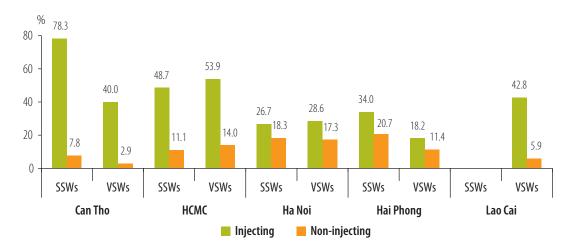

Figure 29: HIV infection among FSWs who injected drugs and who did not inject drugs — IBBS 2009

A significant proportion of FSWs in major urban centers, with the exception of Da Nang, reported that they had had drug-injecting non-commercial sex partners. Over 10% of SSWs in Ha Noi, Quang Ninh, HCMC, Can Tho and Yen Bai reported their regular sex partners injected drugs. SSWs were also much more likely to report sexual partnerships with IDUs than VSWs in all provinces, with the exception of Yen Bai and Da Nang.

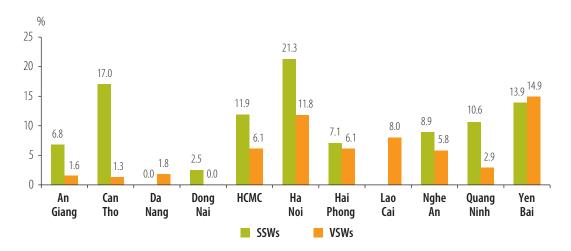

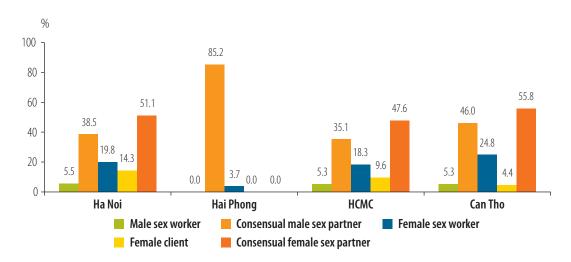

Figure 30: Proportion of FSWs who reported that their regular sex partners inject drugs — IBBS 2009

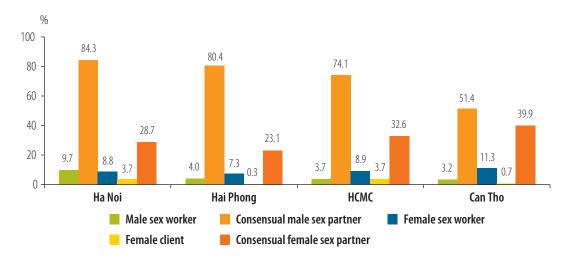

#### 3. Men who have sex with men

MSM were divided into two strata: those who had sold sex for money, and those who had not. MSM from these two categories had considerably different sexual liaisons, especially with respect to consensual male and female sex partners and female sex workers.

**Figure 31a:** Proportion of MSM who sold sex reporting they had sex with a male partner in the last month and a female partner in the last 12 months, by partner type — IBBS 2009

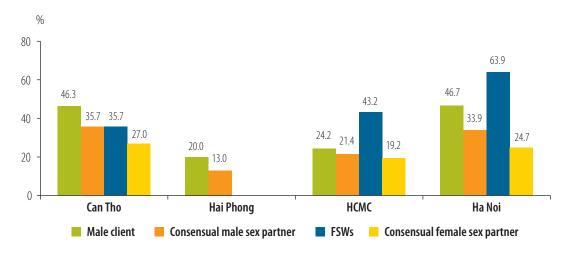

A large proportion of MSM who sold sex said they have had sex with women as consensual sex partners in the past 12 months in three of the four survey provinces. Not including Hai Phong, where MSM who sold sex overwhelmingly have had sex with male sexual partners, 47-56% reported consensual sexual partnerships with women at least once in the past 12 months, versus 35-46% with men at least once in the past month. MSM who sold sex were also more likely to report sex with FSWs (up to 25% in Can Tho) in the past 12 months.

**Figure 31b:** Proportion of MSM who did not sell sex reporting they had sex with a male partner in the last month and a female partner in the last 12 months, by partner type — IBBS 2009

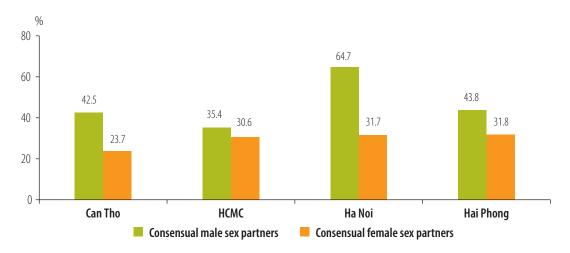

Conversely, only 7-11% of MSM who did not sell sex reported having had sex with FSWs. While these MSM generally preferred consensual male sexual partners, many also reported sexual relations with consensual female partners (from 23-40%) at least once in the past month.

Consistent condom use among MSM who had sold sex with their various partners was low - under 50% in all cities except Ha Noi, where 64% of MSM reported consistent condom use with FSWs. Consistent condom use with consensual female partners (in the last 12 months) was lower than with consensual male partners (in the past one month).

**Figure 32:** Consistent condom use in the past month with male partners and in the last 12 months with consensual male and female sex partners among MSM who had sold sex — IBBS 2009

MSM who did not sell sex reported consistent condom use with both consensual female and male partners even the rate of consistent condom use with consensual female lower than consensual male partner. HCMC had the lowest consistent condom use at 35% in the past month for consensual male partners and Can Tho at 24% for consensual female partners in the past year.

**Figure 33:** Consistent condom use in the past month with consensual male sex partners and in the last 12 months with consensual female sex partners among MSM who did not sell sex — IBBS 2009

Comparisons of data between Rounds I and II show different results for Ha Noi and HCMC. Consistent condom use among MSM who sold sex in Ha Noi was higher in 2009 than in 2006 for all types of partners. Conversely, consistent condom use in HCMC dropped precipitously for male clients and consensual male partners, and dropped from 26% to 19% for consensual female partners.

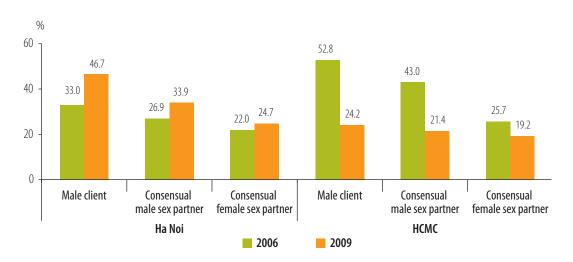

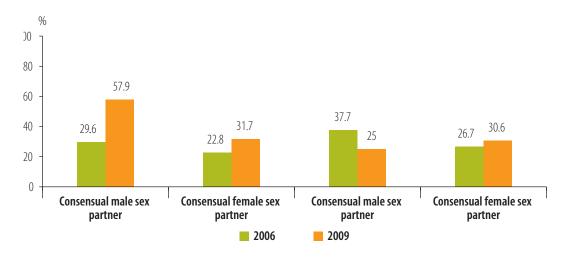

Figure 34: Consistent condom use in the past month with male sex partners and in the last 12 months with consensual male and female sex partner among MSM who had sold sex — IBBS 2006 and 2009

Round I and II comparison data for MSM who did not sell sex in Ha Noi and HCMC were not similar, though not as severe in HCMC. Consistent condom use among MSM who did not sell sex in Ha Noi increased dramatically with consensual male sex partners (more than doubled), and also increased for consensual female partners. HCMC, however, saw reductions in reported consistent condom use with consensual male sex partners from 2006 to 2009.

**Figure 35:** Consistent condom use in the last 12 months with consensual male and female sex partners MSM who did not sell sex – IBBS 2006 and 2009

Like FSWs and IDUs, MSM face drug- and sex-related risks, both of which increase their chances of acquiring HIV. Figure 36 shows the percentage of MSM who reported drug use in 2009. Drug use ranged from one in ten (Can Tho) to one in three (Ha Noi). Reported drug injection was relatively low, the highest proportion in HCMC, at 8%.

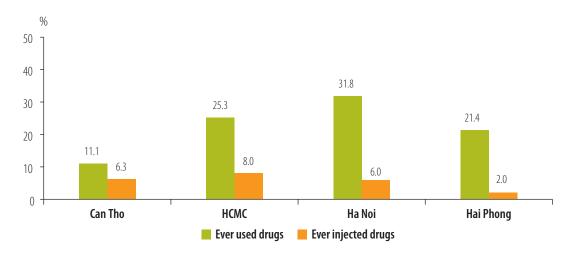

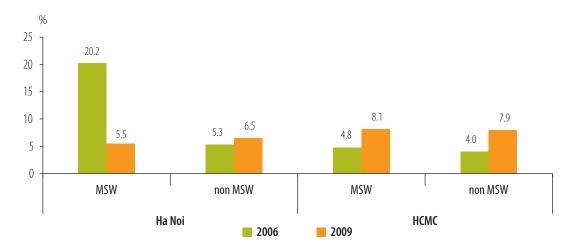

Figure 36: Proportion of MSM who had ever used drugs and who had ever injected drugs

— IBBS 2009

Drug injection practices appear to have changed little between 2006 and 2009, with the exception of MSM who sold sex in Ha Noi. Drug injection among this population was considerably lower in 2009 (from 20% to 5%). Other groups saw slight increases.

**Figure 37:** Injection among MSM who had sold sex (MSW) and who had not sold sex (non MSW) in Ha Noi and HCMC — IBBS 2006 and 2009

Data on drug injection and HIV prevalence among MSM mirror those for FSW: drug injection appears to be associated with HIV infection. More than twice as many drug-injecting MSM were HIV-positive in Ha Noi as opposed to those who did not inject. Data for Can Tho were similar, while MSM who injected in HCMC had slightly higher HIV prevalence than those who did not.

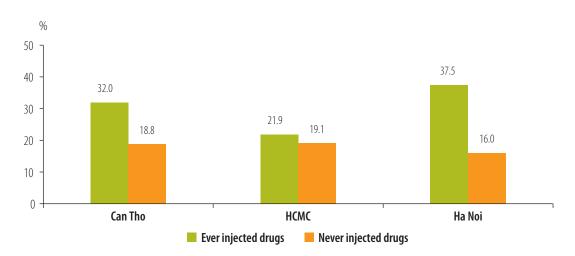

Figure 38: HIV prevalence among MSM who had injected/hadn't injected status — IBBS 2009

#### IV. EXPOSURE TO INTERVENTIONS

This section provides information on coverage of interventions to which respondents were exposed in the last six months. More data on interventions can be found in Appendices 5.8; 6.7; 7.7; 8.7.

In all provinces but Ha Noi, the proportion of IDUs who were tested and were aware of their HIV status was significantly higher in 2009 than in 2006. Quang Ninh and Da Nang saw the largest increases, more than two-fold in Quang Ninh and more than three-fold in Da Nang. Despite these increases, however fewer than 30% of IDUs accessed counseling and testing services in the majority of provinces.

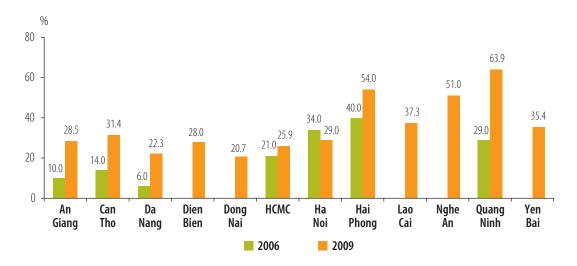

Figure 39: Proportion of IDUs who ever tested for HIV and knew their results

Although HIV testing primarily increased among FSWs, with the exception of Quang Ninh, rates remained low except in a few provinces. In general, more SSWs reported that they had tested for and knew their results than VSWs. The proportion ranged from 3% (Lao Cai) to 86% (Nghe An) for VSWs, versus 21% (Yen Bai) to 79% (Hai Phong) for SSWs. Testing in the newly surveyed provinces of Lao Cai and Yen Bai was significantly lower than the other provinces.

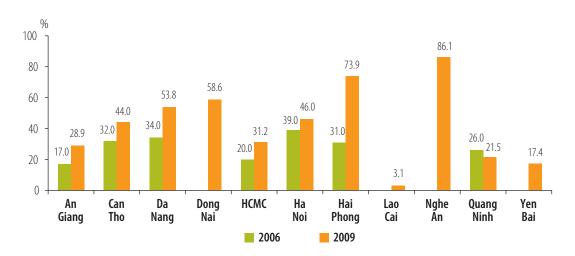

Figure 40a: Proportion of VSWs ever tested for HIV and knew their results

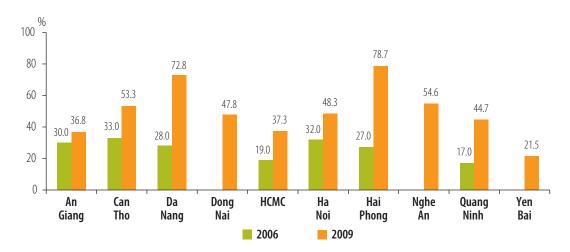

Figure 40b: The proportion of SSWs ever tested for HIV and knew their results

Testing for MSM was also low in all four provinces surveyed. While Ha Noi saw only a slight increase in the proportion of MSM who tested and returned their results from 2006 to 2009, HCMC saw a substantial decrease (from 24% to 19%).

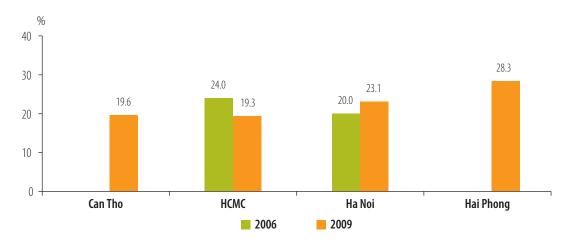

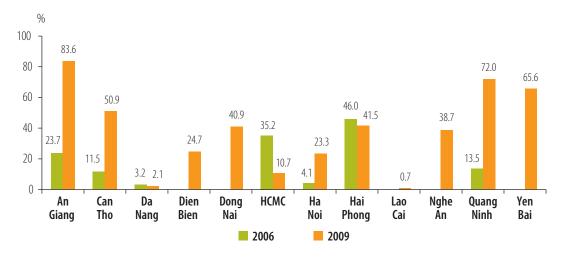

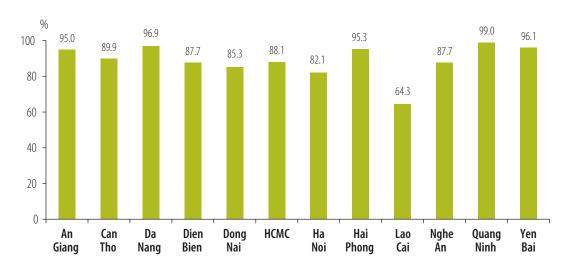

Figure 41: Proportion of MSM ever tested for HIV and knew their results

The proportion of IDUs who accessed free needles and syringes varied widely by provinces. Four of the seven provinces surveyed in 2006 showed substantial increases in 2009 in the proportion of IDUs who reported obtaining free needles and syringes in the last six months. Changes were most significant in Can Tho, Quang Ninh and An Giang, with a three-fold increase in both. Despite these positive changes, obtainment of free needles/syringes in most provinces remained low. Twenty-Three percent of IDUs in Ha Noi reported obtaining free needles and syringes in 2009, 11% in HCMC, and 2% in Da Nang. HCMC saw a significant reduction in reported exposure to free needles and syringes, down from 35% in 2006.

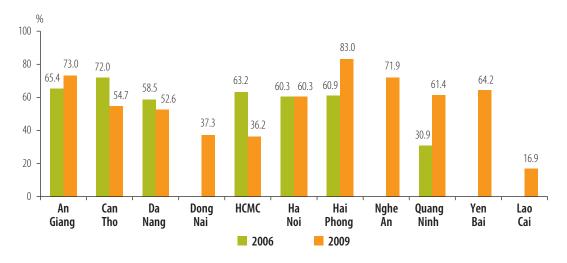

**Figure 42:** Proportion of IDUs who obtained free needles/syringes within the last 6 months – IBBS 2006 and 2009

Despite relatively low obtainment of free needles and syringes in critical provinces, the overwhelming majority of IDUs reported that they were able to purchase or obtain new needles and syringes when needed. Access ranged from 64% in Lao Cai, to up to 99% in provinces surveyed. In most provinces, 80% of IDUs or more reported being able to access free needles and syringes when needed.

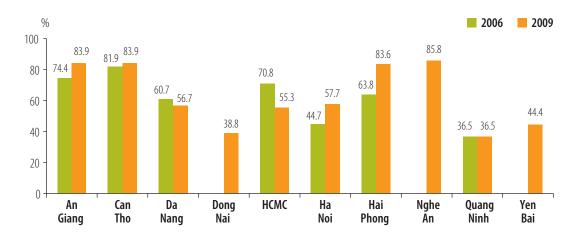

**Figure 43:** Proportion of IDUs who were able to purchase or obtain new needles and syringes when needed — IBBS 2009

The majority of FSWs surveyed in 2009 reported that they had obtained cheap or free condoms in the last six months. However, over 60% of FSWs in HCMC, Lao Cai and Dong Nai reported they had not. Some provinces saw overall reductions in reported access to cheap/ free condoms between 2006 and 2009 (HCMC, Can Tho and Da Nang). Others saw significant overall increases (Hai Phong and An Giang).

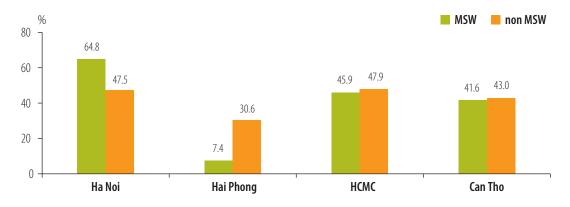

**Figure 44a:** Proportion of VSWs who obtained cheap or free condoms within the last 6 months — IBBS 2006 and 2009

Disaggregation of data for VSWs and SSWs shows significant differences in access to cheap/free condoms for the two subgroups in a number of provinces. Overall, a higher proportion of SSWs reported accessing cheap/free condoms. Over 80% of SSWs in Hai Phong, An Giang, Can Tho and Nghe An reported accessing cheap/free condoms in the last six months.

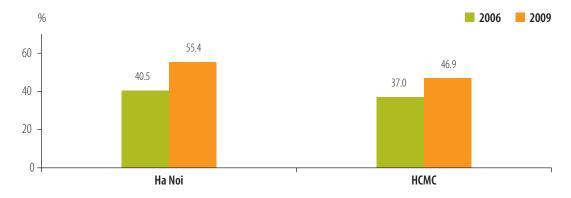

**Figure 44b:** Proportion of SSWs who obtained cheap or free condoms within the last 6 months — IBBS 2006 and 2009

Over 40% of MSM surveyed Ha Noi, HCMC and Can Tho reported obtaining free condoms within the last six months. The proportion of MSM in Hai Phong was comparatively lower, especially among MSM who had sold sex at 7%. A comparison of data from 2006 and 2009 shows that obtainment of free condoms among MSM has slightly increased in Ha Noi and HCMC.

**Figure 45:** Proportion of MSM had sold sex (MSW) and MSM had not sold sex (non MSW) who obtained free condoms in the last six months — IBBS 2009

**Figure 46:** Percentage of MSM who obtained condoms within the last 6 months — IBBS 2006 and 2009

# Study Limitations and Lessons Learned

#### 1. Underestimation of refusals

Individuals selected for participation in the study were given invitation cards to visit the research center. The team calculated the proportion of refusals by dividing the number of cards that were not returned to the research center by the number cards distributed. However, these proportions may actually be higher since a number of selected individuals refused to receive cards; rather than marked as refusals, those cards may have been given to other people to participate. Venue-based sex workers tended to have the highest proportion of refusals, as high as 30% or 40% in some provinces.

#### 2. Self-report bias

The research team employed a number of tactics to limit reporting bias. All interviews were conducted in private, surveys were anonymous, and respondents were encouraged to provide accurate responses. However, respondents may have underreported certain behaviors, particularly those pertaining to drug use and unprotected sex, given the high social stigma of these illicit activities. In most provinces, FSWs reported very high condom use at last sex, while the true figures are likely to be lower. FSWs and MSM may also have underreported drug use, given the dual stigma of sex work and homosexuality with drug use, or over-reported preventive behaviors. As a result, some indicators of risk behaviors are likely to be conservative estimates, while reported preventive behaviors may actually be lower than in the actual population.

Also, given that some of the research centers were located in drop-in centers that provide HIV prevention interventions for most-at-risk populations, individuals who had visited those centers for services were probably more likely to participate than those who had not. As a result of this potential self-reporting bias, the actual coverage of interventions may be lower than observed, and risk behaviors may be higher than observed in this study.

## 3. Representativeness

A few things may have affected the representativeness of the samples. The team conducted random sampling using a sampling frame with mapping process. Mapping was utilized to determine the location where targeted individuals tend to congregate and could be accessed. The field research team was then broken into groups of 3-5 officials to conduct the research (two weeks for each MARP group). Due to limited time and human resources, the teams may have overlooked some mapped spots and not included them in the sample frame. In other cases, researchers were unable to access individuals at mapped locales (e.g. prevented by police raids, entertainment establishment owners...etc.) In addition, "high class" FSWs who charge a higher premium for their services and tend to use mobile phones for arranging meetings do not frequent hotspots, and therefore would not have been included in the sampling frame.

IBBS samples were drawn from the community and did not include those residing in rehabilitation centers at the time of the survey. Therefore, in provinces where a large proportion of IDUs were in rehabilitation centers during the time of the study, the samples may not have been representative of those provinces' IDU populations.

Samples were also drawn from user clubs and community access centers where participation rates are likely to have been higher for individuals who access the services there. In HCMC, for example, roughly one-third of the sample was collected from members of sex worker and MSM clubs. The remaining data were collected from the wider community based out of the research center.

Variance in the selected samples will be larger than those from random sampling because of two effects: the variance among clusters, and the variance between individuals in a cluster. The research team considered this when calculating the sample size, and made adjustments to the following using STATA:

- 1. the sampling probability
- 2. the difference related to the sampling method

### 4. Sampling error

RDS has been widely used as a data collection method for hard-to-reach populations. However, there are a number of assumptions and emerging issues that require further evaluation for this method, including refusal rates, selection of 'seeds', and the extent to which selection can be randomized when using network populations. The reported versus actual size of networks also critically affects outcomes. The bullets below highlight possible sampling errors that may result when RDS is used.

- Certain 'seeds' selected from specific populations (i.e. IDUs) may limit the selection of subjects from sub-groups within those populations. For example, older IDU seeds may be less likely to interact with younger IDUs; working class MSM seeds may have little interaction with MSM in schools.
- One RDS assumption is that seeds and selected subjects will continue to select individuals from their network. However, some individuals do not always recruit members from their network, but rather go to "hot spots" and provide coupons to anyone they meet (even if they do not know each other).
- The rigor with which individuals are selected across sub-groups varies. Sometimes individuals will choose others who are easy to reach, hence they may not be fully representative of their populations.

The team tried to minimize error from this last bullet by adjusting the number of coupons distributed (fewer coupons were distributed in the easier-to-reach networks, while more were distributed in the harder-to-reach networks). However, this approach does not completely eliminate the limitation. For example, forty percent of MSM and sex workers reported that they had acquired representative samples, though the percentage is likely much lower.

## 5. Data analysis bias

The team initially used the Respondent Driven Sampling Analysis Tool (RDSAT, Cornell University, 2003) to analyze the data. This software is designed to adjust data for potential biases that occur in chain-referral recruitment, specifically those due to network and recruitment patterns (Heckathorn 1998). The tool helps produce representative population estimates that, without the tool, would have been considered a convenience sample. However, during the analysis, the research team discovered that RDSAT has some limitations that required further consideration. For example, the analysis has limitations when the number of people in a network is fewer than 100. In addition, RDSAT cannot provide population estimates when sample sizes are below 40. Because of these critical limitations, the team opted not to use RDSAT to analyze the data collected via RDS.

#### 6. Two data points do not necessarily detertmine a trend

With only two points of data collection from 2006 and 2009, the IBBS data currently do not yet reflect a trend. A third round of data collection is needed to allow for a more comprehensive trend analysis. In situations where trend data are needed to drive decision making, results from the IBBS can be combined with other surveys to strengthen our understanding of possible changes in behaviors and prevalence over time.

# Conclusions

### 1. The HIV epidemic in Vietnam remains concentrated

The 2009 IBBS data suggest that the HIV epidemic in Vietnam can be characterized as a series of localized epidemics. Provinces showed wide variation in HIV and STI prevalence, sexual and drug-related risk behaviors, and access to HTC and interventions. Comparison data from the two IBBS rounds also show that provinces vary widely in terms of the potential directions their epidemics are headed across MARP groups.

## 1.1 HIV prevalence stabilized at high levels among MARP groups in most provinces.

- IDUs: Comparison data from the two IBBS rounds show differences in HIV prevalence among IDUs. These differences were not statistically significant in An Giang, Can Tho, Da Nang and Quang Ninh. Conversely, HIV prevalence significantly decreased among IDUs in Hai Phong and Can Tho, and significantly increased in HCMC.
- FSWs: HIV prevalence differed between provinces and between SSW and VSW subgroups. Both SSWs and VSWs had high HIV prevalence in HCMC, Hai Phong and Ha Noi, while HIV prevalence was high particularly for SSWs in Can Tho. Generally, HIV prevalence among sex workers was low in Quang Ninh, Nghe An and Da Nang. Compared to data from IBBS Round I, HIV prevalence among VSWs statistically increased in HCMC, Hanoi, and Hai Phong, and significantly decreased in An Giang. Differences between the two rounds in Can Tho, Da Nang and Quang Ninh were not statistically significant. HIV prevalence among SSWs in IBBS Round II significantly decreased in Can Tho, Hai Phong and Quang Ninh, and increased in HCMC. In An Giang, Da Nang and Hanoi, there was no statistical difference between the two rounds.
- MSM: In IBBS Round II, HIV prevalence among MSM exceeded 10% in Hanoi, Hai Phong and HCMC. Compared to Round 1, HIV prevalence increased in both MSM subgroups (sex workers and non-sex workers), however, the only statistically significant difference was among non-sex workers.

#### 1.2 Sexually transmitted infection prevalence was highest among MSM.

- MSM: STI prevalence remained high among MSM, with no difference between sex worker and non-sex worker subgroups.
- IDUs: Syphilis prevalence was less than 2% among IDUs in all provinces surveyed.
- FSWs: Gonorrhea and syphilis prevalence among FSWs were low, at less than 3% in most provinces surveyed. Compared with IBBS Round I data, STI prevalence among FSWs generally decreased in Hanoi, while prevalence of chlamydia increased among SSWs in HCMC.

#### 2. Risk behaviors

# 2.1 Drug injection and needle and syringe sharing remain major risk behaviors for HIV infection.

- IDUs: Needle and syringe sharing among IDUs was high in most provinces surveyed. Over 20% of IDUs reported having shared needles in the past six months in all provinces except Hai Phong, Can Tho and An Giang.
- FSWs: The proportion FSWs who also inject drugs was high in Hanoi, Hai Phong, HCMC and Can Tho. Drug injection among SSWs was much higher than injection among VSWs.
   Similarly, SSWs were more likely than VSWs to report sex partners who inject drugs.
- MSM: The percentage of MSM who had ever used drugs was high, ranging from 10-32%, the highest in Hanoi. Conversely, the percentage of MSM who had ever injected drugs was low, ranging from 2-8%, the highest in HCMC.

IBBS data suggest that injecting drug use and HIV infection are strongly correlated. Based on data from both rounds, drug injection appears to increase the risk of HIV infection from 1.5 to 10 times for FSW and MSM groups.

#### 2.2 Consistent condom use among all MARP groups remains low.

Despite increases in reported consistent condom use with regular sex partners among all three MARP groups in provinces surveyed, comparison data showed overall stabilized or reduced condom use across all groups.

- IDUs: Consistent condom use in the past 12 months among IDUs was reportedly low with regular partners (wives, girlfriends, partners) and high with FSWs. Compared to IBBS Round I data, consistent condom use with FSWs increased in An Giang and decreased in Quang Ninh. Relatively few HIV-positive IDUs reported unprotected sex with FSWs in the last 12 months.
- FSWs: Similar to data from Round I, FSW condom use with strangers in the last month was significantly higher than with regular customers or regular partners. However, the proportion of consistent condom use with strangers and regular customers in the last month dropped nearly twofold in comparison with 2006 data in Hanoi and HCMC.
- MSM: Only about half of MSM sex workers reported consistent condom use in the last 12 months with customers. Among MSM sex workers who had consensual female sex partners, consistent condom use with female partners was lower than with other partners in most provinces. Consistent condom use among MSM sex workers increased in Hanoi, and decreased in HCMC.

#### 3. Access and utilization of services

# 3.1 Access to, and utilization of HIV testing services remain low.

Despite increases in access and utilization of testing and counseling services for some MARP groups in some provinces, the proportion of MARPs who had ever been tested and received their results was low.

- The percentage of IDUs who had ever been tested and knew their results was significantly higher in 2009 than in 2006 in all provinces except Hanoi. Despite these increases, fewer than 30% of IDUs accessed HIV testing and counseling services in the majority of provinces.
- HIV testing increased among FSWs overall, but remained low in most provinces.
- HIV testing for MSM was low among all MSM groups in surveyed provinces. The percentage of MSM who tested and received their results increased slightly in Hanoi, but dropped considerably in HCMC from 2006 to 2009 (from 24% to 19%).

#### 3.2 Condom and needle/syringe provision remains limited in some locales.

MARP access to, and utilization of, free needles, syringes and condoms varied widely across surveyed provinces.

- Fewer than half of IDUs in 10 of the 12 provinces surveyed had obtained free needles/ syringes in the last six months, and fewer than one-third in six of the provinces. Despite these low figures, many IDUs reported that they could obtain needles and syringes when needed.
- FSW data show promise in some provinces, while others highlight the need for drastic increases in outreach and commodity distribution and social marketing.
- Forty-two to 48% of MSM surveyed in Hanoi, HCMC and Can Tho reported obtaining free condoms within the last six months. However, only 7% of MSM sex workers in Hai Phong had obtained free condoms in the last six months.

# Recommendations

- Although comparison data from Rounds I and II suggest stabilizing or decreasing HIV trends among MARPS in surveyed provinces, more research is needed to estimate the HIV incidence rate among these target groups.
- 2. Expand effective behavior change interventions that promote consistent condom use for FSWs, MSM sex workers, clients of sex workers, and other sexual partners. Special efforts should focus on individuals who have IDU sexual partners. Provinces with particularly low condom use among IDUs (with FSWs and regular sex partners) will require innovation and more efficacious outreach programs. Condom social marketing should be expanded to reach VSWs at karaoke venues, bars, entertainment venues and hotels, and SSWs in zones where they generally congregate. Provinces whose sex workers reported limited access to condoms should develop more aggressive condom social marketing and distribution interventions targeting entertainment venues, karaoke venues, and bars. MSM outreach programs will also need to improve condom social marketing across the board for both subgroups of MSM.
- 3. Strengthen and promote comprehensive drug treatment and prevention interventions, including community-based addictions counseling and methadone treatment, for all eligible individuals. Interventions must expand targeting beyond traditional drug user networks to include MSM and FSWs who inject, or are at risk of injecting drugs.
- 4. Improve access to HIV counseling and testing services for all groups, and ensure appropriate and effective referral to ARV treatment services. HTC promotion and outreach need to focus on individuals whose behaviors are most risky, including those with multiple sex partners, and those who engage in commercial sex and drug injection.
- 5. **Develop innovative, more effective strategies to access and refer MSM.** New strategies are needed to improve MSM community outreach and referral to HTC, condom social marketing, drug use counseling, and HIV care and treatment services.
- 6. **Evaluate more appropriate sampling techniques.** The use of respondent-driven sampling for the IBBS has some limitations, especially with respect to the MSM group. More analysis is needed to determine the appropriate method for sampling among specific MARP groups to overcome these limitations in the future.

Appendix 1: Calculation of sample sizes - IBBS 2009

# Appendix 2: Data weighting in the analysis

Data in the IBBS 2009 survey were weighted to correct for errors that may occur as a result of the sampling design. With time-location sampling, certain venues attract subjects with common characteristics. Therefore, members of different populations have unequal selection probability, resulting in potential sampling error.

#### FSWs example:

Table A2.1 illustrates how weights were obtained using the VSWs sample collected in 2009. The median size estimates were totaled (column B). Each cluster's size estimate was multiplied with the total number of clusters (n=33) and divided by the total population size estimate (n=2097) to obtain the probability of each cluster of women to be selected in the first stage of sampling (column C). In the second stage, each sex worker had a certain probability (column E) of being selected at the venue based on how many women were at the venue during recruitment. Since the number of women found at recruitment was not recorded, the size estimate was used to produce the probability of being selected during the second stage, which is obtained by dividing the number recruited by the size estimate. The probability of selection for each individual (column F) is a product of the probabilities of being selected in the first and second stages (= column C x column E). Finally, the weight is inversely proportional to this product (= 1 / column F). This weight was applied to each interview completed.

**Table A2.1:** Calculation of weights - IBBS 2009

Α	В	C	D	E	F	G
Cluster code	Sample size of cluster estimate	Selection probability - Phase 1	Number of selected subjects	Selection probability - Phase 2	Probability of selection of individual	Weight

# **Appendix 3: Process of HIV diagnostic tests**

#### Requirements:

- 1. HIV testing must be conducted at licensed laboratories which are able to confirm HIV positive result
- 2. Results are given within 2 weeks.
- 3. Compliance of testing protocol

# Test procedure: According to the Ministry of Health Algorithm III

- 1. Screening: Use Determine HIV ½ (Abbott)
  - a. Negative test results: answering "Negative"
  - b. Positive test results: do the additional tests
- 2. Additional tests:
  - a. Genscreen HIV 1 / 2 V.2 (Bio Rad)
  - b. Murex HIV Ag / Ab (Abbott)

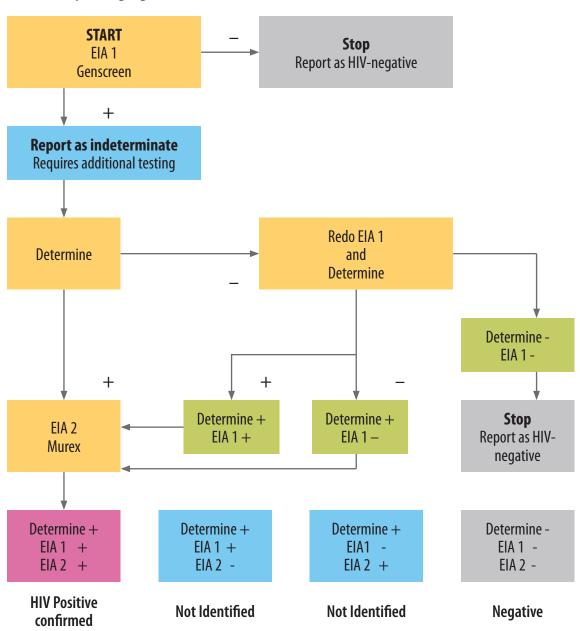

#### **Confirm results:**

- 1. All three techniques give positive results: the conclusion is HIV positive
- 2. If two ELISA techniques give negative results, the conclusion is HIV negative.

# **Quality control for HIV testing**

The National Institute of Hygiene and Epidemiology will take randomly10% HIV-negative samples and 5% HIV-positive samples to re-test.

# **HIV Antibody Testing Algorithm**

# In this study:

- Determine HIV 1 / 2
- EIA 1: Genscreen HIV 1 / 2
- EIA 2: Murex HIV Ag / Ab

# **Appendix 4: Process of diagnostic tests for Syphilis**

#### Requirements:

- 1. The test must be conducted in the laboratory at the provincial level
- 2. Results are given within 2 weeks.
- 3. Compliance of testing protocol

### Testing procedure:

- 1. Screening: RPR Technique (Rapid Plasma Reagin)
  - a. RPR Qualitative:

If negative test results: conclude "Negative"

If positive test results: conduct RPR quantitative test.

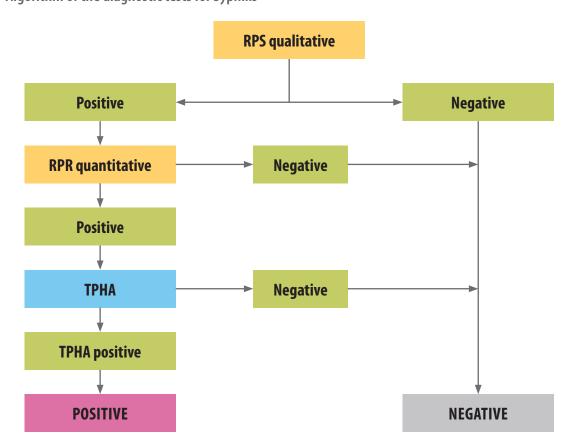

b. Quantitative RPR:

f negative test results: conclude "Negative"

If a positive test results: conduct TPHA test

- 2. Additional tests: TPHA (Treponema pallidum Hemagglutination)
  - a. Negative TPHA results: conclude "Negative"
  - b. Positive TPHA results: conclude "Positive"

# Algorithm of the diagnostic tests for Syphilis
